PREFACE TO ENLARGED EDITION

This thoroughly revised and enlarged edition of Machinery's Handbook contains many standards, tables, rules, formulas and practical data, systematically collated since the publication of earlier editions. The work is enriched by this new material, most of which is published because of repeated requests from engineers, shop executives, and skilled workmen, who have indicated its need in a standard work of reference that is relied upon to contain all the essential working data and fundamental principles of the machine-building industries.

To indicate concisely the extent of this revision, the more important changes may be summarized: The total number of pages has been increased from 1400 to 1592; there are 230 pages of entirely new matter; 97 new tables; 77 new illustrations; 35 revised tables; 55 pages of revised text, exclusive of new material; and several hundred smaller but important changes.

The publishers here express their appreciation and thanks for the co-operation of many friends in the machinery industries, who have assisted in this work of revision by offering practical suggestions or constructive criticisms of former editions. Since Machinery's Handbook was first published in 1914, all letters containing suggestions or material for its improvement have been filed systematically, and have been most valuable in the work of editing this new edition.

For more than ten years, Machinery's Handbook has been a standard reference work for the machinery industries, and the publishers have spared neither labor nor expense to keep it abreast of mechanical progress.

This preface would be incomplete without the names of the men who compiled and edited this book. For the capable and long-continued labors bestowed on this work by Erik Oberg, editor-in-chief, and by Franklin D. Jones, his associate, the publishers here express their sincere thanks and appreciation.

Pi (π). — The ratio of the circumference of a circle to its diameter, which is represented by the Greek letter pi (π), is an incommensurable quantity. The value 3.1416 is accurate enough for ordinary purposes and the value $^{22}/_{7}$ is convenient for rough calculations. The fractions of π given in the above table will be found convenient in certain calculations and also the values in the table of constants on page 76.

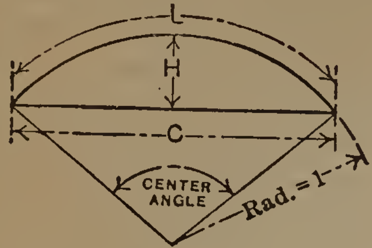
Segments of Circles



Length of Arc, Height of Segment, Length of Chord and Area of Segment for Angles from 1 to 180 degrees, and Radius = 1. — For other radii, multiply the values of *L*, *H* and *C* in the table by the given radius, and the values for areas, by the square of the radius.

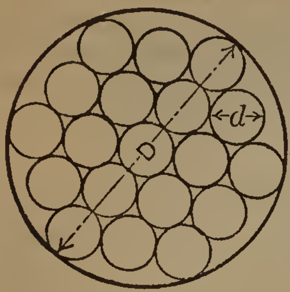
Table of Circles that Can be Inscribed within an Enclosing Circle



From the table below the number of circles of a given diameter that can be inscribed in a larger circle of known diameter, can be found.

N = number of inscribed circles.

$$R = \text{ratio} = \frac{\text{diameter of large circle}}{\text{diameter of small circle}} = \frac{D}{d}.$$

Example: How many wires, ½ inch in diameter, can be placed inside a pipe, 5 inches in diameter? — $R = 5 \div ½ = 10$, and finding the value nearest to this number in the columns of R in the table, $N = 76$ is determined by interpolation.

Approximate Formulas:

$$N = 0.907\left(\frac{D}{d} - 0.94\right)^2 + 3.7 \qquad R = 0.94 + \sqrt{\frac{N - 3.7}{0.907}}$$

Rapid Proof of Multiplications and Divisions

To prove that the product of a multiplication is correct, add together the individual figures in each of the two factors (proceeding to add until a single digit is obtained, as indicated below), and multiply the sum of the figures of one of the factors by the sum of the other factor. This product, reduced by similar addition of digits to one figure, should then equal the sum of the digits in the product.

Example: $3617 \times 2034 = 7{,}356{,}978$.

Adding digits in one factor: $3+6+1+7=17$; $1+7=8$.

Adding digits in other factor: $2+0+3+4=9$.

Multiplying the sums: $8 \times 9 = 72$. Adding digits: $7+2=9$. Adding digits of product: $7+3+5+6+9+7+8=45$; $4+5=9$. The fact that the sum of the digits of the product equals the sum of the digits in the product of the sum of the digits in the factors, is an indication that the product is correct. If the final sums are not equal, the product is incorrect.

A division can be proved in a similar manner, by considering the divisor and quotient as factors, and the dividend as the product.

Example: $131{,}872 \div 317 = 416$.

$3+1+7=11$; $1+1=2$. $4+1+6=11$; $1+1=2$.

Then $2 \times 2 = 4$, and $1+3+1+8+7+2=22$; $2+2=4$.

If there is a remainder, the sum of its digits (reduced to one digit as before) should be added to the product of the final digits of the divisor and quotient. The final digit of this sum should equal the final digit of the dividend.

Lengths of Chords for Spacing off the Circumference of Circles

On the following pages are given tables of the lengths of chords for spacing off the circumference of circles. The object of these tables is to make possible the division of the periphery into a number of equal parts without trials with the dividers. The first table is calculated for circles having a diameter equal to 1. For circles of other diameters, the length of chord given in the table should be multiplied by the diameter of the circle. This first table may be used by toolmakers when setting "buttons" in circular formation. Assume that it is required to divide the periphery of a circle of 20 inches diameter into thirty-two equal parts. From the table the length of the chord is found to be 0.098017 inch, if the diameter of the circle were 1 inch. With a diameter of 20 inches the length of the chord for one division would be $20 \times 0.098017 = 1.9603$ inch.

The two following pages give an additional table for the spacing off of circles, the table, in this case, being worked out for diameters from 1/16 inch to 14 inches. As an example, assume that it is required to divide a circle having a diameter of 6½ inches into seven equal parts. Find first, in the column headed "6" and in line with 7 divisions, the length of the chord for a 6-inch circle, which is 2.604 inches. Then find the length of the chord for a ½-inch diameter circle, 7 divisions, which is 0.217. The sum of these two values, $2.604 + 0.217 = 2.821$ inches, is the length of the chord required for spacing off the circumference of a 6½-inch circle into seven equal divisions.

As another example, assume that it is required to divide a circle having a diameter of 9 23/32 inches into 15 equal divisions. First find the length of the chord for a 9-inch circle, which is 1.871 inch. The length of the chord for a 23/32-inch circle can easily be estimated from the table by taking the value that is exactly between those given for 11/16 and ¾ inch. The value for 11/16 inch is 0.143, and for ¾ inch, 0.156. Hence for 23/32, the value would be 0.150. Then, $1.871 + 0.150 = 2.021$ inches.

Lengths of Chords for Spacing Off the Circumference of Circles with a Diameter Equal to 1

For Circles of Other Diameters Multiply Length Given in Table by Diameter of Circle

Formulas and Table for Regular Polygons

N = number of sides.
S = length of side.
R = radius of circumscribed circle.
r = radius of inscribed circle.
A = area of polygon.
$\alpha = 180° \div N$ = one-half center angle of one side.

Formulas:

$$A = \frac{N \times \cot\alpha \times S^2}{4} = N \times \sin\alpha \times \cos\alpha \times R^2 = N \times \tan\alpha \times r^2$$

$$R = \frac{S}{2\sin\alpha} = \frac{r}{\cos\alpha} \qquad S = 2R \times \sin\alpha = 2r \times \tan\alpha$$

$$r = \frac{S \times \cot\alpha}{2} = R \times \cos\alpha$$

Examples of Use of Table.

A regular hexagon is inscribed in a circle of 6 inches diameter. Find the area and the radius of the inscribed circle. — Here $R = 3$. From the table, area $(A) = 2.5981\ R^2 = 2.5981 \times 9 = 23.3829$ square inches. Radius of inscribed circle, $r = 0.866\ R = 0.866 \times 3 = 2.598$ inches.

Thirty-two bolts are to be equally spaced on the periphery of a bolt-circle, 16 inches in diameter. Find the chordal distance between the bolts. — Chordal distance equals the side (S) of a polygon with 32 sides. $R = 8$. Hence, $S = 0.196\ R = 0.196 \times 8 = 1.568$ inch.

Table for Finding Volume of Spherical Segments

Multiply factor C in table by the cube of the length of the chord of the segment; the product equals the volume.

Center Angle of Segment, Deg.	C	Center Angle of Segment, Deg.	C	Center Angle of Segment, Deg.	C	Center Angle of Segment, Deg.	C	Center Angle of Segment, Deg.	C
3	0.0026	39	0.0341	75	0.0692	111	0.1128	147	0.1739

30	0.0260	66	0.0599	102	0.1008	138	0.1562	174	0.2423
33	0.0287	69	0.0629	105	0.1047	141	0.1619	177	0.2518
36	0.0314	72	0.0660	108	0.1087	144	0.1678	180	0.2618

Example: Find the volume of a spherical segment having a center angle of 30 degrees, if the length of the chord is 10 inches.

$$10^3 \times 0.026 = 1000 \times 0.026 = 26 \text{ cubic inches}$$

Prime Numbers — Factors

The *factors* of a given number are those numbers which when multiplied together give a product equal to that number; thus, 2 and 3 are factors of 6; and 5 and 7 are factors of 35.

A *prime number* is one which has no factors except itself and 1. Thus, 3, 5, 7, 11, etc., are prime numbers. A factor which is a prime number is called a *prime factor*.

The accompanying "Prime Number and Factor Table" gives the smallest prime factor of all odd numbers from 1 to 9600, and can be used for finding all the factors for numbers up to this limit. For example, find the factors of 931. In the column headed "900," and in the line indicated by "31" in the left-hand column, the smallest prime factor is found to be 7. As this leaves another factor 133 (since $931 \div 7 = 133$), find the smallest prime factor of this number. In the column headed "100" and in the line "33," this is found to be 7, leaving a factor 19. This latter is a prime number; hence, the factors of 931 are $7 \times 7 \times 19$. Where no factor is given for a number in the factor table, it indicates that the number is a prime number. Tables of prime numbers and factors are especially useful in calculating the gearing for unusual gear ratios and for spiral gear generating machines, etc.

For factoring, the following general rules will be found useful:

2 is a factor of any number the right-hand figure of which is an even number or 0. Thus, $28 = 2 \times 14$, and $210 = 2 \times 105$.

3 is a factor of any number the sum of the figures of which is evenly divisible by 3. Thus, 3 is a factor of 1869, because $1 + 8 + 6 + 9 = 24$, and $24 \div 3 = 8$.

4 is a factor of any number the two right-hand figures of which, considered as one number, are evenly divisible by 4. Thus, 1844 has a factor 4, because $44 \div 4 = 11$.

5 is a factor of any number the right-hand figure of which is 0 or 5. Thus, $85 = 5 \times 17$; $70 = 5 \times 14$.

Transposition of Formulas

A formula is a rule for a calculation expressed by using letters and signs instead of writing out the rule in words; by this means it is possible to condense, in a very small space, the essentials of long and cumbersome rules. The letters used in formulas simply stand in place of the figures which are to be substituted when solving a specific problem.

An important method for facilitating the use of formulas is known as *transposition.* As an example, the formula for the horsepower transmitted by belting may be written:

$$\text{H.P.} = \frac{SVW}{33{,}000}$$

in which

H.P. = horsepower transmitted;
S = working stress of belt per inch of width, in pounds;
V = velocity of belt in feet per minute;
W = width of belt in inches.

If the working stress S, the velocity V, and the width W, are known, the horsepower can be found directly from this formula by inserting the given values. Assume $S = 33$; $V = 600$; and $W = 5$. Then:

$$\text{H.P.} = \frac{33 \times 600 \times 5}{33{,}000} = 3.$$

Assume, however, that the horsepower, the stress S, and the velocity V are known, and that the width of belt, W, is to be found. The formula must then be transposed so that the symbol W will be on one side of the equals sign and all the known quantities on the other. The transposed formula is as follows:

$$\frac{\text{H.P.} \times 33{,}000}{SV} = W.$$

The quantities (S and V) that were in the numerator on the right side of the equals sign are transposed to the denominator on the left side, and "33,000" which was in the denominator on the right side of the equals sign is transposed to the numerator on the other side. This is in conformity with the general rule for transposition. Symbols which are not part of a fraction, like "H.P." in the formula first given, are to be considered as being numerators (having the denominator 1).

According to the rule given, any formula of the form $A = \frac{B}{C}$ can be transposed as below:

$$A \times C = B, \quad \text{and} \quad C = \frac{B}{A}$$

Suppose a formula to be of the form:

$$A = \frac{B \times C}{D}$$

Then:

$$D = \frac{B \times C}{A}; \quad \frac{A \times D}{C} = B; \quad \frac{A \times D}{B} = C.$$

The method given is only directly applicable when all the quantities in the numerator or denominator are standing independently or are *factors of a product.* If connected by + or − signs, the transposition can be made by the method shown only when the *whole sum* or *difference* is transposed.

Example:

$$A = \frac{B + C}{D}; \quad \text{then} \quad D = \frac{B + C}{A} \quad \text{and} \quad A \times D = B + C.$$

A quantity preceded by a + or − sign can be transposed to the opposite side of the equals sign by changing its sign; if the sign is +, change it to − on the other side; if it is −, change it to +.

Example:

$$B+C=A-D;\quad \text{then}\quad B+C+D=A;$$
$$B=A-D-C;$$
$$C=A-D-B;$$
$$D=A-B-C.$$

When several numbers or quantities in a formula are connected with signs indicating that additions, subtractions, multiplications or divisions are to be made, the multiplications should be carried out before any of the other operations. Division also precedes addition and subtraction if written in line with these. The other operations are carried out in the order written.

Examples:

$$10+26\times 7-2=10+182-2=190.$$
$$18\div 6+15\times 3=3+45=48.$$
$$12+14\div 2-4=12+7-4=15.$$

When it is required that certain additions and subtractions should precede multiplications and divisions, use is made of parentheses ( ) and brackets [ ]. These indicate that the calculation inside the parentheses or brackets should be carried out complete by itself before the remaining calculations are commenced. If one bracket is placed inside of another, the one inside is first calculated.

Examples:

$$(6-2)\times 5+8=4\times 5+8=20+8=28.$$
$$6\times(4+7)\div 22=6\times 11\div 22=66\div 22=3.$$
$$2+[10\times 6(8+2)-4]\times 2=2+[10\times 6\times 10-4]\times 2$$
$$=2+[600-4]\times 2=2+596\times 2=2+1192=1194.$$

The parentheses are considered as a sign of multiplication; for example, $6\,(8+2) = 6\times(8+2)$.

The line or bar between the numerator and denominator in a fractional expression is to be considered as a division sign. For example,

$$\frac{12+16+22}{10}=(12+16+22)\div 10=50\div 10=5.$$

In formulas the multiplication sign (×) is often left out between symbols or letters, the values of which are to be multiplied. Thus

$$AB=A\times B,\quad \text{and}\quad \frac{ABC}{D}=(A\times B\times C)\div D$$

Ratio and Proportion

The *ratio* between two quantities is the quotient obtained by dividing the first quantity by the second. For example, the ratio between 3 and 12 is $\frac{1}{4}$, and the ratio between 12 and 3 is 4. Ratio is generally indicated by the sign (:); thus 12 : 3 indicates the ratio of 12 to 3.

A *reciprocal* or *inverse* ratio is the reciprocal of the original ratio. Thus, the inverse ratio of 5 : 7 is 7 : 5.

In a *compound* ratio each term is the product of the corresponding terms in two or more simple ratios. Thus, when

$$8:2=4,\qquad 9:3=3,\qquad 10:5=2,$$

then the compound ratio is:

$$8\times 9\times 10:2\times 3\times 5=4\times 3\times 2,$$
$$720:30=24.$$

Proportion is the equality of ratios. Thus,

$$6 : 3 = 10 : 5, \quad \text{or} \quad 6 : 3 :: 10 : 5.$$

The first and last terms in a proportion are called the *extremes;* the second and third, the *means.* The product of the extremes is equal to the product of the means. Thus,

$$25 : 2 = 100 : 8 \quad \text{and} \quad 25 \times 8 = 2 \times 100.$$

If three terms in a proportion are known, the remaining term may be found by the following rules:

The first term is equal to the product of the second and third terms, divided by the fourth.

The second term is equal to the product of the first and fourth terms, divided by the third.

The third term is equal to the product of the first and fourth terms, divided by the second.

The fourth term is equal to the product of the second and third terms, divided by the first.

Examples: — Let x be the term to be found, then,

$$x : 12 = 3.5 : 21 \qquad x = \frac{12 \times 3.5}{21} = \frac{42}{21} = 2$$

$$\tfrac{1}{4} : x = 14 : 42 \qquad x = \frac{\frac{1}{4} \times 42}{14} = \frac{1}{4} \times 3 = \frac{3}{4}$$

$$5 : 9 = x : 63 \qquad x = \frac{5 \times 63}{9} = \frac{315}{9} = 35$$

$$\tfrac{1}{4} : \tfrac{7}{8} = 4 : x \qquad x = \frac{\frac{7}{8} \times 4}{\frac{1}{4}} = \frac{3\frac{1}{2}}{\frac{1}{4}} = 14.$$

If the second and third terms are the same, either is said to be the *mean proportional* between the other two. Thus, $8 : 4 = 4 : 2$, and 4 is the mean proportional between 8 and 2. The mean proportional between two numbers may be found by multiplying the numbers together, and extracting the square root of the product. Thus, the mean proportional between 3 and 12 is found as below:

$$3 \times 12 = 36, \quad \text{and} \quad \sqrt{36} = 6,$$

which is the mean proportional.

Practical Examples Involving Simple Proportion. — If it takes 18 days to assemble 4 lathes, how long would it require to assemble 14 lathes?

Let the number of days to be found be x. Then write out the proportion as below:

$$4 : 18 = 14 : x$$
$$(\text{lathes} : \text{days} = \text{lathes} : \text{days})$$

Find now the fourth term by the rule given:

$$x = \frac{18 \times 14}{4} = 63 \text{ days.}$$

Thirty-four linear feet of bar stock are required for the blanks for 100 clamping bolts. How many feet of stock would be required for 912 bolts?

Let x = total length of stock required for 912 bolts.

$$34 : 100 = x : 912$$
$$(\text{feet} : \text{bolts} = \text{feet} : \text{bolts})$$

Then, the third term $x = \dfrac{34 \times 912}{100} = 310$ feet, approximately.

Example of Inverse Proportion. — A factory employing 270 men completes a given number of typewriters weekly, the number of working hours being 60 per week. How many men would be required for the same production if the working hours were reduced to 54 per week?

The time per week is in an inverse proportion to the number of men employed; the *shorter* the time, the *more* men. The inverse proportion is written:

$$270 : x = 54 : 60$$

(men, 10-hour basis : men, 9-hour basis = time, 9-hour basis : time, 10-hour basis)

The second term $x = \dfrac{270 \times 60}{54} = 300$ men.

Example of Compound Proportion. — If a man capable of turning 65 studs in a day of 10 hours is paid 32.5 cents per hour, how much ought a man be paid who turns 72 studs in a 9-hour day, if compensated in the same proportion?

When solving problems involving compound proportion, the following method of analysis tends to simplify the solution. Make up a table with four columns headed, "First Cause," "First Effect," "Second Cause," "Second Effect," and place under each the respective factors given in the problem. In the example above, the table would be arranged as below:

First Cause	First Effect	Second Cause	Second Effect
1 man 10 hours 32.5 cents	65 studs	1 man 9 hours x cents	72 studs

Consider as *causes* the number of men working, the length of time they work, and their capacity for work; the pay received or the amount of product turned out in a unit of time indicates the capacity for work. The effect is the total product given either in numbers, or by the dimensions of the work carried out. The unknown quantity is called x.

When the table is completed, take all the quantities in the first and fourth columns and place them as the numerator of a fraction with multiplication signs between them, and all the quantities in the second and third columns and place them as the denominator of a fraction with multiplication signs between them. Put this fraction equal to 1. Then cancel and reduce the fraction to its simplest form as below.

$$\frac{1 \times 10 \times 32.5 \times 72}{65 \times 1 \times 9 \times x} = 1; \quad \frac{40}{x} = 1, \text{ or } x = 40 \text{ cents.}$$

Percentage

If out of 100 pieces made, 12 do not pass inspection, it is said that 12 per cent (12 on the hundred) are rejected. If a quantity of steel is bought for $100 and sold for $140, the profit is 40 per cent.

The per cent of gain or loss is found by dividing the amount of gain or loss by the *original* number of which the percentage is wanted, and multiplying the quotient by 100.

Examples: — Out of a total output of 280 castings a day, 30 castings are, on an average, rejected. What is the percentage of bad castings?

$$\frac{30}{280} \times 100 = 10.7 \text{ per cent.}$$

If by a new process 100 pieces can be made in the same time as 60 could formerly be made, what is the gain in output of the new process over the old, expressed in per cent?

Original number, 60; gain $100 - 60 = 40$. Hence,

$$\frac{40}{60} \times 100 = 66.7 \text{ per cent.}$$

Care should be taken always to use the original number, or the number of which the percentage is wanted, as the divisor in all percentage calculations. In the example just given, it is the percentage of gain over the old output 60 that is wanted, and not the percentage with relation to the new output 100. Mistakes are often made by overlooking this important point.

Interest

Interest is the money paid for the use of money lent for a certain time. *Simple* interest is the interest paid on the principal (money lent) only. When simple interest that is due is not paid, and its amount is added to the interest-bearing principal, the interest calculated on this new principal is called *compound* interest. The compounding of the interest into the principal may take place yearly or oftener, according to circumstances.

Simple Interest. — The following formulas are applicable to the calculations involving simple interest. Let:

P = principal or amount of money lent;
p = per cent of interest;
r = interest rate = the interest, expressed decimally, on $1.00 for one year = the per cent of interest divided by 100; thus, if the interest is 6 per cent, the rate $r = 6/100 = 0.06$;
n = the number of years for which interest is calculated;
I = the amount of interest for n years at the given rate;
P_n = principal with interest for n years added, or the total amount after n years.

Then:

Interest for n years, $I = Prn$.
Total amount after n years, $P_n = P + Prn = P(1 + rn)$.
Interest rate $r = I \div Pn$.
Number of years $n = I \div Pr$.
Principal, or amount lent $= I \div rn$.

Example: — Assume that $250 has been loaned for three years at 6 per cent simple interest. Then: $P = 250$; $p = 6$; $r = p \div 100 = 0.06$; $n = 3$.

$$I = Prn = 250 \times 0.06 \times 3 = \$45.$$
$$P_n = P + I = 250 + 45 = \$295.$$

The accurate interest for one day is 1/365 of the interest for one year. Banks, however, customarily take the year as composed of 12 months of 30 days, making a total of 360 days to a year.

Compound Interest. — The following formulas are applicable when compound interest is to be computed, using the same notation as for simple interest, and assuming that the interest is compounded annually.

The total amount after n years, $P_n = P(1 + r)^n$.

The principal $P = \dfrac{P_n}{(1 + r)^n}$ The rate $r = \sqrt[n]{\dfrac{P_n}{P}} - 1$

The number of years during which the money is lent

$$n = \frac{\log P_n - \log P}{\log (1 + r)}$$

Logarithms are especially useful in calculating compound interest. To find the total amount P_n of principal and interest after n years, the formula just given can be transcribed as below:

$$\log P_n = \log P + n \log (1 + r).$$

If the interest is payable q times a year, it will be computed q times during each year, or nq times during n years. The rate for each compounding will be $r \div q$, if r is the annual rate. Hence, at the end of n years the amount due will be:

$$P_n = P \left(1 + \frac{r}{q}\right)^{nq}$$

Thus, if the term be five years, the interest be payable quarterly, and the annual rate be 6 per cent, then, $n = 5$; $q = 4$; $r = 0.06$; $r \div q = 0.06 \div 4 = 0.015$; and $nq = 5 \times 4 = 20$.

Example: — In what time will \$500 become \$1000 at 6 per cent interest compounded yearly?

$$P_n = 1000; \quad P = 500; \quad r = 0.06.$$

Substituting these values in the formula:

$$1000 = 500\,(1 + 0.06)^n, \quad \text{or} \quad 2 = 1.06^n, \quad \text{and} \quad n \times \log 1.06 = \log 2.$$

Hence
$$n = \frac{0.30103}{0.02531} = 11.9 \text{ years.}$$

This is the number of years in which any principal will double itself at 6 per cent compound interest.

Present Value and Discount. — The present value V of a given amount due in a given time, is the sum which placed at interest for the given time, will produce the given amount. Hence,

$$\text{At simple interest, } V = \frac{P_n}{1 + nr}$$

$$\text{At compound interest, } V = \frac{P_n}{(1 + r)^n}$$

in which P_n is the amount due in n years time, and r is the rate of simple interest, or the per cent divided by 100.

The *true discount* D is the difference between the amount due at the end of n years and the present value, or,

$$\text{At simple interest, } D = P_n - V = \frac{P_n nr}{1 + nr}$$

$$\text{At compound interest, } D = P_n - V = P_n \left[1 - \frac{1}{(1 + r)^n}\right]$$

These formulas are for interest compounded annually. If the interest is payable and compounded semi-annually, or quarterly, modify the formulas as indicated in the formulas for compound interest.

Example: — Required the present value and discount of $500 due in six months at 6 per cent simple interest. Here, $P_n = 500$; $n = 6/12$ years $= 1/2$; $r = 0.06$; then,

$$V = \frac{500}{1 + 0.5 \times 0.06} = \$485.44.$$

$$D = 500 - 485.44 = \$14.56.$$

Example: — Required the sum which placed at 5 per cent compound interest, will in three years produce $5000. Here, $P_n = 5000$; $r = 0.05$; $n = 3$. Then,

$$V = \frac{5000}{(1 + 0.05)^3} = 4319.19.$$

Bank discount is calculated at simple interest on the total amount of a promissory note for the term of the note and on the basis of a year of 360 days.

Annuities. — An annuity is a fixed sum paid at regular intervals. In the formulas given below, yearly payments are assumed. It is customary to calculate annuities on the basis of compound interest.

If an annuity A is to be paid out for n consecutive years, the interest rate being r, then the present value P of the annuity is:

$$P = A\,\frac{(1 + r)^n - 1}{(1 + r)^n r}$$

Example: — If an annuity of $200 is to be paid for 10 years, what is the present amount of money that need be deposited if the interest is 5 per cent? Here,

$$A = 200; \quad r = 5 \div 100 = 0.05; \quad n = 10.$$

$$P = 200\,\frac{1.05^{10} - 1}{1.05^{10} \times 0.05} = 1544.36.$$

The annuity that a principal P, drawing interest at the rate r, will give for a period of n years, is:

$$A = \frac{Pr\,(1 + r)^n}{(1 + r)^n - 1}$$

Example: — A sum of $10,000 is placed at 4 per cent interest. What is the amount of the annuity which can be paid for 20 years out of this sum? Here,

$$P = 10{,}000; \quad r = 0.04; \quad n = 20.$$

$$A = \frac{10{,}000 \times 0.04 \times 1.04^{20}}{1.04^{20} - 1} = 735.82.$$

If at the beginning of each year a sum A is set aside at an interest rate r, then the total value of the sum set aside, with interest, will be at the end of n years:

$$P_n = A\,\frac{(1 + r)\,[(1 + r)^n - 1]}{r}$$

If at the end of each year a sum A is set aside at an interest rate r, then the total value of the principal, with interest, at the end of n years will be:

$$P_n = A\,\frac{(1 + r)^n - 1}{r}$$

If a principal P is increased or decreased by a sum A at the end of each year, then the value of the principal after n years will be:

$$P_n = P\,(1 + r)^n \pm A\,\frac{(1 + r)^n - 1}{r}$$

If the sum A by which the principal P is decreased each year is greater than the total yearly interest on the principal, then the principal, with the accumulated interest, will be entirely used up in n years:

$$n = \frac{\log A - \log (A - Pr)}{\log (1 + r)}$$

Sinking Funds.— Amortization is "the extinction of a debt, usually by means of a sinking fund." The sinking fund is created by a fixed investment S placed annually at compound interest for a term of years, and is hence an annuity of sufficient size to produce at the end of the term of years the amount necessary for the repayment of the principal of the debt, or to provide a definite sum for other purposes. Let:

S = the annual investment;

r = rate of interest (the per cent divided by 100);

P = the amount of the sinking fund;

n = the number of years for its creation.

Then:

$$P = S\frac{(1+r)^n - 1}{r}, \quad \text{and} \quad S = \frac{Pr}{(1+r)^n - 1}$$

which formulas correspond to those given above, where a sum A was laid aside at the end of each year.

Example: — If $2000 is invested annually for 10 years, at 4 per cent compound interest, as a sinking fund, what would be the total amount of the fund at the expiration of the term? Here, $S = 2000$; $n = 10$; $r = 0.04$.

$$P = 2000\frac{1.04^{10} - 1}{0.04} = 24{,}012.25$$

Alligation

When an alloy is composed of several metals varying in price, the price per pound of the alloy can be found as in the following example: An alloy is composed of 50 pounds of copper at 14 cents a pound, 10 pounds of tin at 29 cents a pound, 20 pounds of zinc at 5 cents a pound, and 5 pounds of lead at 4 cents a pound. What is the cost of the alloy per pound, no account being taken of the cost of mixing it?

Multiply the number of pounds of each of the ingredients by its price per pound, add these products together, and divide the sum by the total weight of all the ingredients. The quotient is the price per pound of the alloy.

$50 \times 14 + 10 \times 29 + 20 \times 5 + 5 \times 4 = 700 + 290 + 100 + 20 = 1110.$

Total weight of metal in alloy = $50 + 10 + 20 + 5 = 85$.

Price per pound of alloy = $1110/85 = 13$ cents, approximately.

In general, let a, b, c and d be the weights of each of the ingredients, and w, x, y and z be their respective values per unit weight. Then the average price P per unit weight of the alloy is found by the formula:

$$P = \frac{aw + bx + cy + dz}{a + b + c + d}$$

Example: — Find the average price per pound of an alloy containing 40 pounds of tin at 30 cents per pound, 48 pounds of lead at 4 cents per pound, 10 pounds of antimony at 8 cents per pound, and 2 pounds of copper at 15 cents per pound.

$$P = \frac{40 \times 30 + 48 \times 4 + 10 \times 8 + 2 \times 15}{40 + 48 + 10 + 2} = \frac{1502}{100} = 15.02 \text{ cents.}$$

Formulas for Arithmetical Progression

To Find	Given	Use Equation
a	$d \quad l \quad n$	$a = l - (n-1)d$
	$d \quad n \quad S$	$a = \frac{S}{n} - \frac{n-1}{2} \times d$
	$d \quad l \quad S$	$a = \frac{d}{2} \pm \frac{1}{2}\sqrt{(2l+d)^2 - 8dS}$
	$l \quad n \quad S$	$a = \frac{2S}{n} - l$
d	$a \quad l \quad n$	$d = \frac{l-a}{n-1}$
	$a \quad n \quad S$	$d = \frac{2S - 2an}{n(n-1)}$
	$a \quad l \quad S$	$d = \frac{l^2 - a^2}{2S - l - a}$
	$l \quad n \quad S$	$d = \frac{2nl - 2S}{n(n-1)}$
l	$a \quad d \quad n$	$l = a + (n-1)d$
	$a \quad d \quad S$	$l = -\frac{d}{2} \pm \frac{1}{2}\sqrt{8dS + (2a-d)^2}$
	$a \quad n \quad S$	$l = \frac{2S}{n} - a$
	$d \quad n \quad S$	$l = \frac{S}{n} + \frac{n-1}{2} \times d$
n	$a \quad d \quad l$	$n = 1 + \frac{l-a}{d}$
	$a \quad d \quad S$	$n = \frac{d-2a}{2d} \pm \frac{1}{2d}\sqrt{8dS + (2a-d)^2}$
	$a \quad l \quad S$	$n = \frac{2S}{a+l}$
	$d \quad l \quad S$	$n = \frac{2l+d}{2d} \pm \frac{1}{2d}\sqrt{(2l+d)^2 - 8dS}$
S	$a \quad d \quad n$	$S = \frac{n}{2}[2a + (n-1)d]$
	$a \quad d \quad l$	$S = \frac{a+l}{2} + \frac{l^2 - a^2}{2d} = \frac{a+l}{2d}(l + d - a)$
	$a \quad l \quad n$	$S = \frac{n}{2}(a+l)$
	$d \quad l \quad n$	$S = \frac{n}{2}[2l - (n-1)d]$

Arithmetical Progression

An arithmetical progression is a series of numbers in which each consecutive term differs from the preceding one by a fixed amount called the *common difference, d*. Thus, 1, 3, 5, 7, etc., is an arithmetical progression where the difference d is 2. The difference in this case is *added* to the preceding term, and the progression is called increasing. In the series 13, 10, 7, 4, etc., the difference is (-3), and the progression is called decreasing. In any arithmetical progression (or part of progression) let

a = the first term considered;
l = the last term considered;
n = the number of terms;
d = the common difference;
S = the sum of n terms.

Then the general formulas are:

$$l = a + (n - 1)\,d \quad \text{and} \quad S = \frac{a+l}{2} \times n$$

In these formulas d is positive in an increasing and negative in a decreasing progression. When any three of the five quantities above are given, the other two can be found by the formulas in the accompanying table of arithmetical progression.

Example: — In an arithmetical progression, the first term equals 5, and the last term 40. The difference is 7. Find the sum of the progression.

$$S = \frac{a+l}{2d}(l + d - a) = \frac{5+40}{2 \times 7}(40 + 7 - 5) = 135.$$

Geometrical Progression

A geometrical progression or a geometrical series is a series in which each term is derived by multiplying the preceding term by a constant multiplier called the *ratio*. When the ratio is greater than 1, the progression is increasing; when smaller than 1, it is decreasing. Thus, 2, 6, 18, 54, etc., is an increasing geometrical progression with a ratio of 3, while 24, 12, 6, etc., is a decreasing progression with a ratio of ½.

In any geometrical progression (or part of progression) let

a = the first term;
l = the last (or nth) term;
n = the number of terms;
r = the ratio of the progression;
S = the sum of n terms.

Then the general formulas are:

$$l = ar^{n-1} \quad \text{and} \quad S = \frac{rl - a}{r - 1}$$

When any three of the five quantities above are given, the other two can be found by the formulas tabulated in the accompanying table. Geometrical progressions are used for finding the successive speeds in machine tool drives, in interest calculations, etc.

Example: — The lowest speed of a lathe is 20 R.P.M. The highest speed is 225 R.P.M. There are 18 speeds. Find the ratio between successive speeds.

$$\text{Ratio, } r = \sqrt[n-1]{\frac{l}{a}} = \sqrt[17]{\frac{225}{20}} = \sqrt[17]{11.25} = 1.153.$$

Formulas for Geometrical Progression

To Find	Given	Use Equation
a	$l \quad n \quad r$	$a = \dfrac{l}{r^{n-1}}$
	$n \quad r \quad S$	$a = \dfrac{(r-1)S}{r^n - 1}$
	$l \quad r \quad S$	$a = lr - (r-1)S$
	$l \quad n \quad S$	$a(S-a)^{n-1} = l(S-l)^{n-1}$
l	$a \quad n \quad r$	$l = ar^{n-1}$
	$a \quad r \quad S$	$l = \dfrac{1}{r}[a + (r-1)S]$
	$a \quad n \quad S$	$l(S-l)^{n-1} = a(S-a)^{n-1}$
	$n \quad r \quad S$	$l = \dfrac{S(r-1)r^{n-1}}{r^n - 1}$
n	$a \quad l \quad r$	$n = \dfrac{\log l - \log a}{\log r} + 1$
	$a \quad r \quad S$	$n = \dfrac{\log[a + (r-1)S] - \log a}{\log r}$
	$a \quad l \quad S$	$n = \dfrac{\log l - \log a}{\log(S-a) - \log(S-l)} + 1$
	$l \quad r \quad S$	$n = \dfrac{\log l - \log[lr - (r-1)S]}{\log r} + 1$
r	$a \quad l \quad n$	$r = \sqrt[n-1]{\dfrac{l}{a}}$
	$a \quad n \quad S$	$r^n = \dfrac{Sr}{a} + \dfrac{a-S}{a}$
	$a \quad l \quad S$	$r = \dfrac{S-a}{S-l}$
	$l \quad n \quad S$	$r^n = \dfrac{Sr^{n-1}}{S-l} - \dfrac{l}{S-l}$
S	$a \quad n \quad r$	$S = \dfrac{a(r^n - 1)}{r - 1}$
	$a \quad l \quad r$	$S = \dfrac{lr - a}{r - 1}$
	$a \quad l \quad n$	$S = \dfrac{\sqrt[n-1]{l^n} - \sqrt[n-1]{a^n}}{\sqrt[n-1]{l} - \sqrt[n-1]{a}}$
	$l \quad n \quad r$	$S = \dfrac{l(r^n - 1)}{(r-1)r^{n-1}}$

Mathematical Signs and Commonly Used Abbreviations

$+$	Plus (sign of addition)	
$+$	Positive	
$-$	Minus (sign of subtraction)	
$-$	Negative	
$\pm$ ($\mp$)	Plus or minus (minus or plus)	
$\times$	Multiplied by (multiplication sign)	
$\cdot$	Multiplied by (multiplication sign)	
$\div$	Divided by (division sign)	
$:$	Divided by (division sign)	
$:$	Is to (in proportion)	
$=$	Equals	
$::$	Equals (in proportion)	
$\cong$	Approximately equals	
$>$	Greater than	
$<$	Less than	
$\geqq$	Greater than or equal to	
$\leqq$	Less than or equal to	
$\therefore$	Therefore	
$\sqrt{\ }$	Square root	
$\sqrt[3]{\ }$	Cube root	
$\sqrt[4]{\ }$	4th root	
$\sqrt[n]{\ }$	*n*th root	
a^2	*a* squared (2d power of *a*)	
a^3	*a* cubed (3d power of *a*)	
a^4	4th power of *a*	
a^n	*n*th power of *a*	
$\frac{1}{n}$	Reciprocal value of *n*	
log	Logarithm	
hyp. log nat. log $\log_e$ ln	Hyperbolic, natural or Napierian logarithm	
lim.	Limit value (of an expression)	
∞	Infinity	
α	Alpha	commonly used to denote angles
β	Beta	
γ	Gamma	
θ	Theta	
ϕ	Phi	
Δ	Delta (difference)	
δ	Delta (differential)	
μ	Mu (coefficient of friction)	
π	Pi (3.1416)	
Σ	Sigma (sign of summation)	
ω	Omega (angles measured in radians)	
d	Differential (in calculus)	
e	Base of hyp. logarithms (2.71828)	

g	Acceleration due to gravity (32.16 ft. per sec.)
i	Imaginary quantity ($\sqrt{-1}$)
sin	Sine
cos	Cosine
tan (tg) (tang)	Tangent
cot (ctg)	Cotangent
sec	Secant
cosec	Cosecant
versin	Versed sine
covers	Coversed sine
$\sin^{-1} a$ arc sin a	Arc the sine of which is a
$(\sin a)^{-1}$	Reciprocal of sin a ($1 \div \sin a$)
$\sinh x$	Hyperbolic sine of x
$\cosh x$	Hyperbolic cosine of x
$\int$	Integral (in calculus)
$\int_b^a$	Integral between the limits a and b
!	$5! = 1 \times 2 \times 3 \times 4 \times 5$
$\angle$	Angle
$\llcorner$	Right angle
$\perp$	Perpendicular to
$^\circ$	Degree (circular arc or thermometer)
$'$	Minutes or feet
$''$	Seconds or inches
a'	*a* prime
a''	*a* double prime
a_1	*a* sub one
a_2	*a* sub two
a_n	*a* sub *n*
( )	Parentheses
[ ]	Brackets
{ }	Braces
B.H.P.	Brake horsepower
B.T.U.	British thermal units
H.P.	Horsepower
I.H.P.	Indicated horsepower
K.W.	Kilowatt
M.E.P.	Mean effective pressure
R.P.M.	Revolutions per minute
C.G.S.	Centimeter-gram-second system

Greek Letters

The Greek letters are frequently used in mathematical expressions and formulas. The Greek alphabet is given below.

Α	α	Alpha	Η	η	Eta	Ν	ν	Nu	Τ	τ	Tau
Β	β	Beta	Θ	ϑ θ	Theta	Ξ	ξ	Xi	Υ	υ	Upsilon
Γ	γ	Gamma	Ι	ι	Iota	Ο	o	Omicron	Φ	ϕ	Phi
Δ	δ	Delta	Κ	κ	Kappa	Π	π	Pi	Χ	χ	Chi
Ε	ϵ	Epsilon	Λ	λ	Lambda	Ρ	ρ	Rho	Ψ	ψ	Psi
Ζ	ζ	Zeta	Μ	μ	Mu	Σ	σ ς	Sigma	Ω	ω	Omega

Positive and Negative Numbers

The degrees on a thermometer scale extending upward from the zero point may be called *positive* and may be preceded by a plus sign; thus $+5$ degrees means 5 degrees above zero. The degrees below zero may be called *negative* and may be preceded by a minus sign; thus -5 degrees means 5 degrees below zero. In the same way, the ordinary numbers 1, 2, 3, etc., which are larger than 0, are called positive numbers; but numbers can be conceived of as extending in the other direction from 0, numbers that, in fact, are less than 0, and these are called negative. As these numbers must be expressed by the same figures as the positive numbers they are designated by a minus sign placed before them, thus: (-3). A negative number should always be enclosed within parentheses whenever it is written in line with other numbers; for example: $17+(-13)-3\times(-0.76)$.

Negative numbers are most commonly met with in the use of logarithms and natural trigonometric functions. The following rules govern calculations with negative numbers.

A negative number can be added to a positive number by subtracting its numerical value from the positive number.

Example: $4+(-3)=4-3=1.$

A negative number can be subtracted from a positive number by adding its numerical value to the positive number.

Example: $4-(-3)=4+3=7.$

A negative number can be added to a negative number by adding the numerical values and making the sum negative.

Example: $(-4)+(-3)=-7.$

A negative number can be subtracted from a negative number by subtracting the numerical values and making the difference negative.

Example: $(-4)-(-3)=-1.$

If in a subtraction the number to be subtracted is larger than the number from which it is to be subtracted, the calculation can be carried out by subtracting the smaller number from the larger, and indicating that the remainder is negative.

Example: $3-5=-(5-3)=-2.$

When a positive number is to be multiplied or divided by a negative number, multiply or divide the numerical values as usual; the product or quotient, respectively, is negative. The same rule is true if a negative number is multiplied or divided by a positive number.

Examples: $4\times(-3)=-12;\quad(-4)\times 3=-12;$

$15\div(-3)=-5;\quad(-15)\div 3=-5.$

When two negative numbers are to be multiplied by each other, the product is positive. When a negative number is divided by a negative number, the quotient is positive.

Examples: $(-4) \times (-3) = 12$; $(-4) \div (-3) = 1.333$.

The two last rules are often expressed for memorizing as follows: "Equal signs make plus, unequal signs make minus."

Powers and Roots

The *square* of a number is the product of that number multiplied by itself. Thus, the square of 9 is $9 \times 9 = 81$. The square of a number is indicated by the *exponent* (^{2}), thus: $9^2 = 9 \times 9 = 81$.

The *cube* or *third power* of a number is obtained if the number itself is repeated as a factor three times. Thus, the cube of 4 is $4 \times 4 \times 4 = 64$, and is written 4^3.

If a number is repeated as a factor four or five times, respectively, the product is the fourth or fifth power. Thus $3^4 = 3 \times 3 \times 3 \times 3 = 81$, and $2^5 = 2 \times 2 \times 2 \times 2 \times 2 = 32$. A number can be raised to any power by repeating it as a factor the required number of times.

The *square root* of a given number is that number which, when multiplied by itself, will give a product equal to the given number. The square root of 16 (written $\sqrt{16}$) equals 4, because $4 \times 4 = 16$.

The *cube root* of a given number is that number which, when repeated as a factor three times, will give a product equal to the given number. Thus, the cube root of 64 (written $\sqrt[3]{64}$) equals 4, because $4 \times 4 \times 4 = 64$.

The fourth, fifth, etc., roots of a given number are those numbers which when repeated as factors four, five, etc., times, will give as a product the given number. Thus $\sqrt[4]{16} = 2$, because $2 \times 2 \times 2 \times 2 = 16$.

The multiplications required for raising numbers to powers and the extracting of roots are greatly facilitated by the use of logarithms. The extracting of the square root and cube root by the regular arithmetical methods is a slow and cumbersome operation, and any roots can be more rapidly found by using logarithms.

The tables of squares and cubes, and square roots and cube roots, found at the beginning of this book, give these values directly for all whole numbers up to 2000. For ordinary practical calculations the squares, cubes, etc., for fractional values between whole numbers can usually be estimated. These tables also give the *reciprocals* of numbers from 1 to 2000. The reciprocal of a number is the quotient obtained by dividing 1 by the number. Thus the reciprocal of 4 is $1 \div 4 = 0.25$. The reciprocal values given in the tables can be used to save labor in division, as the quotient can be obtained by multiplying the dividend by the reciprocal of the divisor. Thus, the reciprocal of 244 is 0.0040984. To divide 13 by 244, or to reduce $13/244$ to a decimal, multiply as follows: $13 \times 0.0040984 = 0.0532792$.

Extracting the Square Root. — Assume that the square root of 119,716 is to be found. Beginning at the unit figure or decimal point, point off the number into periods of two figures each. Should there be an odd number of figures in the given number, the last period to the left will have only one figure.

Find the greatest whole number, the square of which does not exceed the value of the figures in the left-hand period (11), and write this number as the first figure in the root. In this example, this number is 3, the square of which is 9. Subtract this square from the left-hand period, and move down the next period of two figures and annex it to the remainder.

$$\begin{array}{rr|l} & 11'97'16 & 346 \\ 3 \times 3 = & 9 & \\ \hline 3 \times 20 = 60 & 297 & \\ (60 + 4) \times 4 = & 256 & \\ \hline 34 \times 20 = 680 & 4116 & \\ (680 + 6) \times 6 = & 4116 & \\ \hline \end{array}$$

Multiply the figure of the root obtained by the constant 20; $(3 \times 20 = 60)$; find how many times this product is contained in the number 297. This gives a trial figure for the second figure of the root; 60 is contained 4 whole times in 297, and 4 is, therefore, placed as the next figure of the root.

Subtract from 297 the product of 60 plus the figure of the root just obtained (4), multiplied by the same figure (4); $(60 + 4) \times 4 = 256$. If this product were larger than 297 it would indicate that the trial figure is too large, and a figure one unit smaller should be used. Then move down the next period of two figures and annex it to the remainder.

Multiply the figures of the root thus far obtained by 20; $(34 \times 20 = 680)$; find how many times this product is contained in 4116. This gives a trial figure for the third figure of the root. Then proceed as before.

If the last subtraction leaves no remainder, and if there are no more periods of figures to move down from the given number, the obtained root 346 is the exact square root of 119,716. If there is a remainder when the last period of figures has been moved down, place a decimal point after the figures already obtained in the root, annex two ciphers (00) to the remainder, and proceed as before until a sufficient number of decimals have been obtained.

Extracting the Cube Root. — Assume that the cube root of 80,621,568 is to be found. Beginning at the unit figure or decimal point, point off the number into periods of three figures each.

$$\begin{array}{rr|l} & 80'621'568 & 432 \\ 4 \times 4 \times 4 = & 64 & \\ \hline 4^2 \times 300 = 4{,}800 & 16621 & \\ 4^2 \times 300 \times 3 + 4 \times 30 \times 3^2 + 3^3 = & 15507 & \\ \hline 43^2 \times 300 = 554{,}700 & 1114568 & \\ 43^2 \times 300 \times 2 + 43 \times 30 \times 2^2 + 2^3 = & 1114568 & \\ \hline \end{array}$$

Find the greatest whole number, the cube of which does not exceed the value of the figures in the left-hand period (80), and write this number as the first figure in the root; 4 is the greatest whole number the cube of which does not exceed 80; subtract the cube of 4 from the left-hand period and move down the next period of three figures, and annex it to the remainder.

Multiply the square of the figure in the root by the constant 300; $(4^2 \times 300 = 4800)$, and find how many times this product is contained in the number 16,621. This gives a trial figure for the second figure of the root.

Now subtract from 16,621 the *sum* of the following products:

1. The square of the figure or figures already obtained in the root, except the last one, multiplied by 300 and this product multiplied by the figure just obtained in the root: $4^2 \times 300 \times 3 = 16 \times 300 \times 3 = 14{,}400$.

2. The figure or figures already obtained in the root, except the last one, multiplied by 30, and this product multiplied by the square of the last figure obtained: $4 \times 30 \times 3^2 = 4 \times 30 \times 9 = 1{,}080$.

3. The cube of the last figure obtained: $3^3 = 3 \times 3 \times 3 = 27$.

If the sum of these various products is larger than 16,621, it indicates that the trial figure is too large, and a figure one unit smaller should be used. After having subtracted as directed, move down the next period of three figures, and annex it to the remainder, and proceed as before.

Principal Algebraic Expressions and Formulas

$$a \times a = aa = a^2$$
$$a \times a \times a = aaa = a^3$$
$$a \times b = ab$$
$$a^2b^2 = (ab)^2$$
$$a^2a^3 = a^{2+3} = a^5$$
$$a^4 \div a^3 = a^{4-3} = a$$
$$a^\circ = 1$$
$$a^2 - b^2 = (a+b)(a-b)$$
$$(a+b)^2 = a^2 + 2\,ab + b^2$$
$$(a-b)^2 = a^2 - 2\,ab + b^2$$
$$\frac{a^3}{b^3} = \left(\frac{a}{b}\right)^3$$
$$\frac{1}{a^3} = \left(\frac{1}{a}\right)^3 = a^{-3}$$
$$(a^2)^3 = a^{2\times 3} = (a^3)^2 = a^6$$
$$a^3 + b^3 = (a+b)(a^2 - ab + b^2)$$
$$a^3 - b^3 = (a-b)(a^2 + ab + b^2)$$
$$(a+b)^3 = a^3 + 3\,a^2b + 3\,ab^2 + b^3$$
$$(a-b)^3 = a^3 - 3\,a^2b + 3\,ab^2 - b^3$$

$$\sqrt{a} \times \sqrt{a} = a$$
$$\sqrt[3]{a} \times \sqrt[3]{a} \times \sqrt[3]{a} = a$$
$$(\sqrt[3]{a})^3 = a$$
$$\sqrt[3]{a^2} = (\sqrt[3]{a})^2 = a^{\frac{2}{3}}$$
$$\sqrt[4]{\sqrt[3]{a}} = \sqrt[4\times 3]{a} = \sqrt[3]{\sqrt[4]{a}}$$
$$\sqrt{a} + \sqrt{b} = \sqrt{a + b + 2\sqrt{ab}}$$
$$\sqrt[3]{ab} = \sqrt[3]{a} \times \sqrt[3]{b}$$
$$\sqrt[3]{\frac{a}{b}} = \frac{\sqrt[3]{a}}{\sqrt[3]{b}}$$
$$\sqrt[3]{\frac{1}{a}} = \frac{1}{\sqrt[3]{a}} = a^{-\frac{1}{3}}$$

When $a \times b = x$, then $\log a + \log b = \log x$

$a \div b = x$, then $\log a - \log b = \log x$

$a^3 = x$, then $3 \log a = \log x$

$\sqrt[3]{a} = x$, then $\dfrac{\log a}{3} = \log x$

Equations

An equation is a statement of equality between two expressions, as $5\,x = 105$. The unknown quantity in an equation is generally designated by the letter x. If there is more than one unknown quantity, the others are designated by letters also selected at the end of the alphabet, as y, z, u, t, etc.

An equation of the first degree is one which contains the unknown quantity only in the first power, as $3\,x = 9$. A quadratic equation is one which contains the unknown quantity in the second, but no higher, power, as $x^2 + 3\,x = 10$.

Solving Equations of the First Degree with One Unknown. — Transpose all the terms containing the unknown x to one side of the equals sign, and all the other terms to the other side. Combine and simplify the expressions as far as possible, and divide both sides by the coefficient of the unknown x. (See the rules given for transposition of formulas.)

Example:

$$22\,x - 11 = 15\,x + 10$$
$$22\,x - 15\,x = 10 + 11$$
$$7\,x = 21$$
$$x = 3$$

Solution of Equations of the First Degree with Two Unknowns. — The form of the simplified equations is:

$$ax + by = c$$
$$a_1x + b_1y = c_1$$

Then,

$$x = \frac{cb_1 - c_1b}{ab_1 - a_1b} \qquad y = \frac{ac_1 - a_1c}{ab_1 - a_1b}$$

Example:

$$3x + 4y = 17$$
$$5x - 2y = 11$$
$$x = \frac{17 \times (-2) - 11 \times 4}{3 \times (-2) - 5 \times 4} = \frac{-34 - 44}{-6 - 20} = \frac{-78}{-26} = 3.$$

The value of y can now be most easily found by inserting the value of x in one of the equations:

$$5 \times 3 - 2y = 11; \quad 2y = 15 - 11 = 4; \quad y = 2.$$

Solution of Quadratic Equations with One Unknown. — If the form of the simplified equation is:

$$x^2 + px = q, \quad \text{then} \quad x = -\frac{p}{2} \pm \sqrt{\frac{p^2}{4} + q}$$

If the form of the equation is:

$$ax^2 + bx = c, \quad \text{then} \quad x = \frac{-b \pm \sqrt{b^2 + 4ac}}{2a}$$

Example 1:

$$x^2 + 12x = 108$$
$$x = -\frac{12}{2} \pm \sqrt{\frac{144}{4} + 108} = -6 \pm \sqrt{36 + 108} = -6 \pm \sqrt{144} = -6 \pm 12$$
$$x = 6, \quad \text{or} \quad x = -18.$$

Example 2:

$$3x^2 - 15x = 0.$$
$$x = \frac{+15 \pm \sqrt{225 + 0}}{2 \times 3} = \frac{15 \pm 15}{6}.$$
$$x = \frac{30}{6} = 5, \quad \text{or} \quad x = \frac{0}{6} = 0.$$

Cubic Equations. — If the given equation has the form:

$$x^3 + ax + b = 0$$

then,

$$x = \left(-\frac{b}{2} + \sqrt{\frac{a^3}{27} + \frac{b^2}{4}}\right)^{\frac{1}{3}} + \left(-\frac{b}{2} - \sqrt{\frac{a^3}{27} + \frac{b^2}{4}}\right)^{\frac{1}{3}}$$

The equation $x^3 + px^2 + qx + r = 0$, may be reduced to the form $x_1^3 + ax_1 + b = 0$, by substituting $x_1 - \frac{p}{3}$ for x in the given equation.

THE SLIDE-RULE

By means of the slide-rule, various calculations may be made mechanically with greater ease and rapidity than by ordinary arithmetical methods, and usually with sufficient accuracy for all practical requirements. Slide-rules are used principally for performing multiplication and division, but they may also be used for finding powers, roots, logarithms, and trigonometrical functions, and for various other purposes. The slide-rule in its most common form consists of three main parts. There is a main body or rule, a slide, and a runner or "cursor." Scales *A* and *D* (see Fig. 1) are on the rule, and scales *B* and *C* on the slide. Fig. 1 shows the right-hand half of the rule and the left-hand half of the slide, this sectional view being shown in order to secure a larger reproduction. The runner, which is in the form of a light metal frame that is free to slide endwise along the rule, is also shown in Fig. 1. Scales *A* and *B* are alike, as are scales *C* and *D*. All four scales are of the same length, but the graduations on scales *A* and *B* are different from those on scales *C* and *D*. The graduation 1 (seen at the extreme left in Fig. 1) is in the center of the rule, and scale *A* has two parts on opposite sides of this middle point 1 that are graduated exactly alike. The left-hand half from 1 to 1 is called the *left-hand A scale*, and the right-hand half from 1 to 1, the *right-hand A scale*. As scale *B* is exactly like scale *A*, its sections are designated as the *left-hand B scale* and the *right-hand B scale*. Each end of each scale is marked by the figure 1 which is known as the *index*. Thus, the figure 1 at the left-hand end of a scale is called the *left-hand index*, and figure 1 at the right-hand end is called the *right-hand index*.

As will be seen, the divisions on a slide-rule are not uniform. For example, that part of the left-hand *D* scale between divisions 1 and 2 (see enlarged detailed view, Fig. 2) is divided into ten main parts, no two of which are equal. Nevertheless, each of these main spaces represents 0.1. Each main space is subdivided into ten unequal parts, each of which represents one-tenth of 0.1, or 0.01. On the scales *A* and *B*, each of the ten main spaces between 1 and 2 is divided into only five parts; therefore, each subdivision represents 0.02. It is not possible to divide the spaces between graduations 4 and 5, 6 and 7, 8 and 9, etc., into as many parts as between 1 and 2, or 2 and 3, because the graduation lines would be too close together; therefore, the subdivisions near the right-hand end of any of the scales represent greater values than those near the left-hand end. This fact must be kept in mind or errors will result in the use of the slide-rule.

Reading the Slide-rule Graduations. — The method of reading the graduations is indicated in Fig. 2. A small figure 1 to the right of the left-hand index 1, represents the value 1.1, the small figure 2 marks the line that represents 1.2, and so on, to the small figure 9, which denotes 1.9. The second line to the right of the left-hand index denotes 1.02, as it is the second of the ten marks between 1 and 1.1. Several other lines at different points of the scale have the values indicated. It will be noticed that in each case the reading is accurate to at least three figures, and in some cases to four. The divisions on all four of the scales on the slide-rule are such that values can be read correctly to three figures; but beyond this it is not possible to proceed accurately, although the fourth figure may be obtained by estimating with the eye the fractional part of the subdivision. For instance, the fourth figure of the reading 1.535 is possible because the point is halfway between 1.53 and 1.54.

The values of these readings are based on the assumption that the left-hand index represents 1. The value of the left-hand index of any scale may be taken as any power of 0.1 or of 10; that is, it may be taken to represent 0.1, 0.01, 0.001, etc., or 10, 100, 1000, etc. If the left-hand index of the *D* scale represents 0.01, the readings in Fig. 2 must be multiplied by 0.01, so that they become 0.0102,

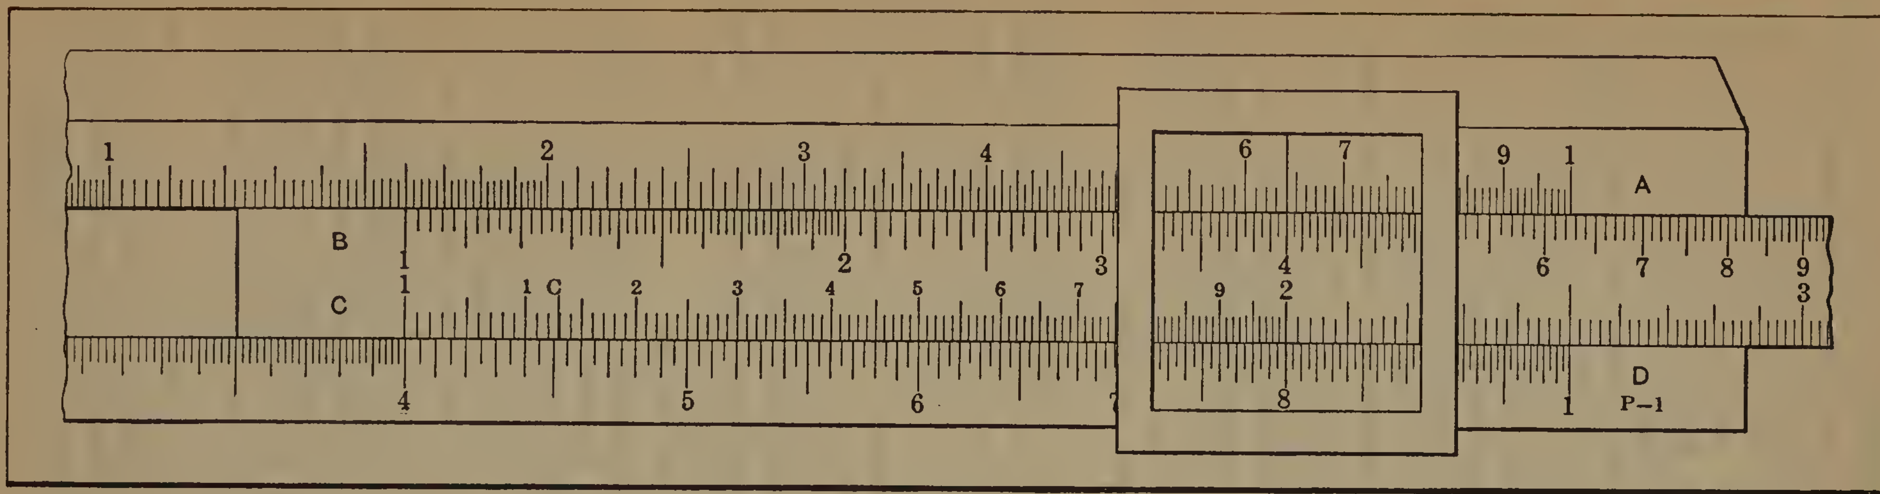

Fig. 1

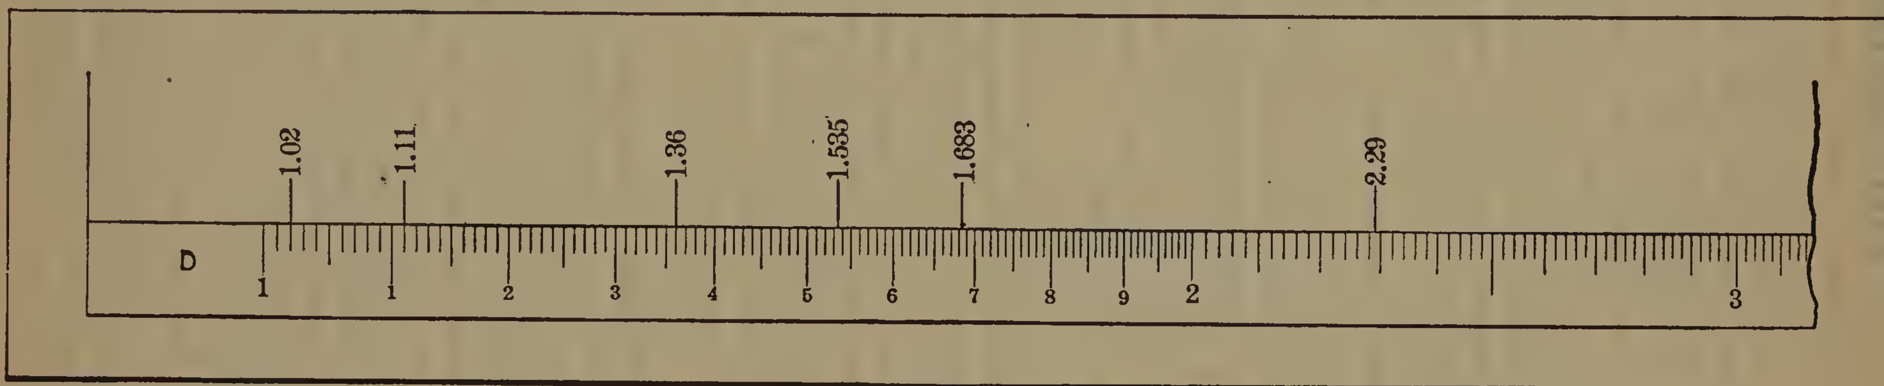

Fig. 2

0.0111, 0.0136, 0.01535, 0.01683, and 0.0229. If the left-hand index represents 1000, the readings must be multiplied by 1000. When a value has been assigned to the index, the same ratio must be maintained throughout the remainder of the scale, a line on any scale always representing the same sequence of figures, but not always the same value. The scales *C* and *D* have a greater number of subdivisions between two consecutive numbers than have the scales *A* and *B* between the same numbers; therefore, it is customary to use the *C* and *D* scales for multiplications and divisions, as they can be read with greater ease and accuracy.

Multiplication of Whole Numbers. — In multiplying two numbers with the slide-rule, one index of the *C* scale is set opposite one of the numbers on the *D* scale, and the product is read on the *D* scale directly in line with the other number on the *C* scale.

Example: — Find the product of 4×2. Move the slide to the right, as shown in Fig. 1, until the left-hand index of the *C* scale is exactly in line with 4 on the *D* scale; then, directly opposite 2 on the *C* scale, read the product, 8, on the *D* scale. The hair-line on the glass plate of the runner should be used, as shown, to determine what reading on the *D* scale is opposite 2 on the *C* scale.

Example: — Find the product of 7×2. If the left-hand index of the *C* scale is set to 7 on the *D* scale, the 2 on the *C* scale will be far to the right of the end of the *D* scale, and no result can be read. In such a case as this, move the slide to the left until the right-hand index of the *C* scale is opposite 2 on the *D* scale; then, opposite 7 on the *C* scale will be found the small figure 4 on the *D* scale, which is the point corresponding to 1.4; but 1.4 is not the product of 7 and 2, as $7 \times 2 = 14$. However, neglecting the decimal point, the figures of the result are correct. It becomes evident, therefore, that while the slide-rule will correctly show the first two, three, or four figures of the result, it will not always indicate the correct number of figures preceding the decimal point. The following simple rule may be used to find the number of figures in the product of two whole numbers:

Rule: — If the result is obtained with the slide projecting to the left, the number of figures in the product is equal to the sum of the numbers of figures in the two numbers; but, if the slide projects to the right, the number of figures in the product is one less than the sum of the numbers of figures in the two numbers.

For instance, apply this rule to the example illustrated by Fig. 1. In this case, each number contains one figure, and the slide projects to the right; therefore, the number of figures in the result must be $(1 + 1) - 1 = 1$.

Example: — Let the product of 223×7285 be required. Set the right-hand index of the *C* scale to 223 on the *D* scale, as shown in Fig. 3. It is not possible to determine the exact point on the *C* scale corresponding to 7285, as that scale, between 7 and 8, can be read accurately to only two figures, while the third must be approximated. So the runner is set with its hair-line at the position corresponding to 729 on the *C* scale, as nearly as can be judged. Below, on the *D* scale, the hair-line points to 1625, as nearly as can be read; hence, 1625 forms the first four figures of the result. As the slide projects to the left, the product must contain $3 + 4 = 7$ figures, according to the rule. Therefore the first four figures 1625 must be increased to seven by the addition of ciphers at the right, giving 1,625,000. The actual product, worked out in the usual way, is 1,624,555, which shows that the slide-rule gives the correct result to the third figure.

Multiplication of Decimals. — If the numbers to be multiplied are decimals or mixed numbers, disregard the decimal points for the time being and treat each as a whole number. Find the product of the whole numbers as already explained, and then point off as many decimal places as there are in both original numbers.

Example: — Let the product of 335.75×0.00264 be required. Neglecting the decimal points, these numbers become 33,575 and 264. As the scales cannot be read accurately to more than three places, the first of the numbers may be written 33,600. Set the left-hand index of the *C* scale to 336 on the *D* scale, and opposite 264 on the *C* scale, as indicated by the hair-line, read 886 on the *D* scale. As the slide projects to the right, the number of figures in the product is $5 + 3 - 1 = 7$; that is, four ciphers must be added to the three figures read on the *D* scale, giving 8,860,000 as the product of 33,600 and 264 on the rule. But the original numbers, 335.75 and 0.00264, have two decimal places and five decimal places, respectively, or seven decimal places in all; hence, seven places must be pointed off in the product of the whole numbers, giving 0.8860000, or simply 0.886, as the required result.

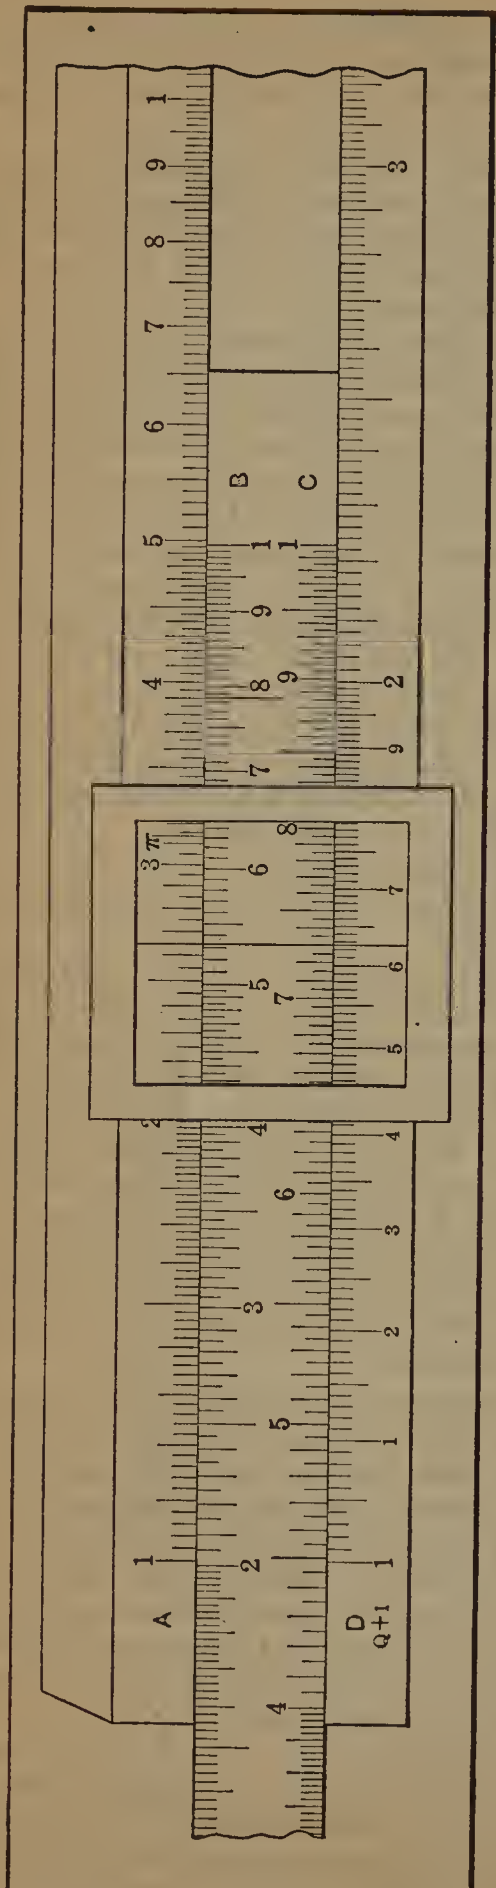

Fig. 3

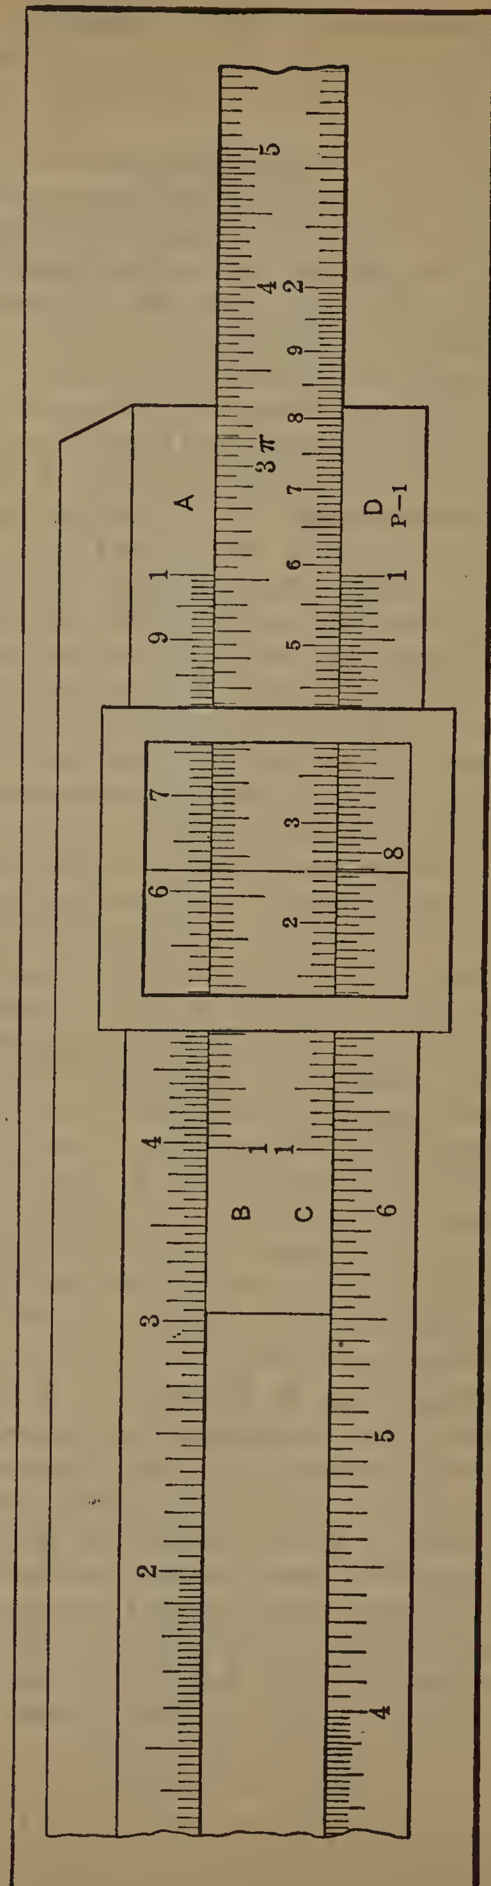

Fig. 4

Continued Multiplication. — Continued multiplication can be performed very quickly by the use of the slide-rule. For example, suppose that the result of $6.3 \times 1.25 \times 965.5 \times 0.47$ is required. Neglecting decimal points for the time being, and writing all the numbers as whole numbers, the problem becomes $63 \times 125 \times 9655 \times 47$. Set the left-hand index of the *C* scale to 63 on the *D* scale and move the runner until the hair-line is over 125 on the *C* scale, as shown in Fig. 4. Now, without disturbing the runner, move the slide to the left until the right-hand index of the *C* scale is under the hair-line, and then, leaving the slide stationary, move the runner until the hair-line is over 9655 on the *C* scale. Finally, without moving the runner set the slide with the right-hand index of the *C* scale under the hair line. Then, without moving the slide, set the hair-line over 47 on the *C* scale. The result, read on the *D* scale under the hair-line, is 357. In obtaining this result, however, the slide projected once to the right and twice to the left; so taking the sum of the numbers of figures in all the factors, treated as whole numbers, and subtracting 1 for the time that the slide projected to the right, the number of figures in the product is found to be $(2 + 3 + 4 + 2) - 1 = 10$; that is, the product of the whole numbers is 3,570,000,000. But, the original factors contain $1 + 2 + 1 + 2 = 6$ decima places, which must be pointed off in the final result; hence, the required product is 3570.000000, or simply 3570.

In this example there are three settings of the slide, each representing one process of multiplication. The first gives the product of 63 and 125; the second gives the product of (63×125) and 9655; and the third gives the product of $(63 \times 125 \times 9655)$ and 47. The hair-line on the runner serves to designate the product obtained at each setting.

Division of Whole Numbers. — Division is simply a reversal of multiplication. The number to be divided, or the dividend, is found on the *D* scale, and the hair-line of the runner is set over it. The divisor is found on the *C* scale and is set directly under the hair-line, also. The quotient is then read from the *D* scale at a point opposite the index of the *C* scale. In performing the division of whole numbers by the aid of the slide-rule, two cases may arise: The dividend may exceed the divisor or the divisor may exceed the dividend. If the dividend is the greater, the quotient will be a whole number or a mixed number. To find the number of figures in the whole-number part of the quotient, the following simple rule may be used:

Rule: — If the slide projects to the left, the number of figures in the whole-number part of the quotient is equal to the difference between the number of figures in the dividend and the number of figures in the divisor; but, if the slide projects to the right, the number of figures in the whole-number part of the quotient is 1 plus this difference.

Example: — To illustrate the application of this rule, suppose that the quotient of $1325 \div 592$ is required. Set the runner so that the hair-line is directly over 1325 on the *D* scale, as in Fig. 5. Next, without moving the runner, set the slide so that 592 on the *C* scale is directly under the hair-line. Then, opposite the right-hand index of the *C* scale will be found 224 on the *D* scale. As there are four figures in the dividend and three in the divisor, and the slide projects to the left, the number of figures in the whole-number part of the quotient, according to the rule, is $4 - 3 = 1$; therefore, the result is 2.24.

When Divisor is Greater than Dividend. — If the divisor is greater than the dividend, a different rule must be used, because the result will then be wholly a decimal. The slide and the runner are set in the same way as previously described, but the decimal point is located according to the following rule:

Rule: — If the slide projects to the left, the number of ciphers between the decimal point and the first figure of the quotient is equal to the difference between

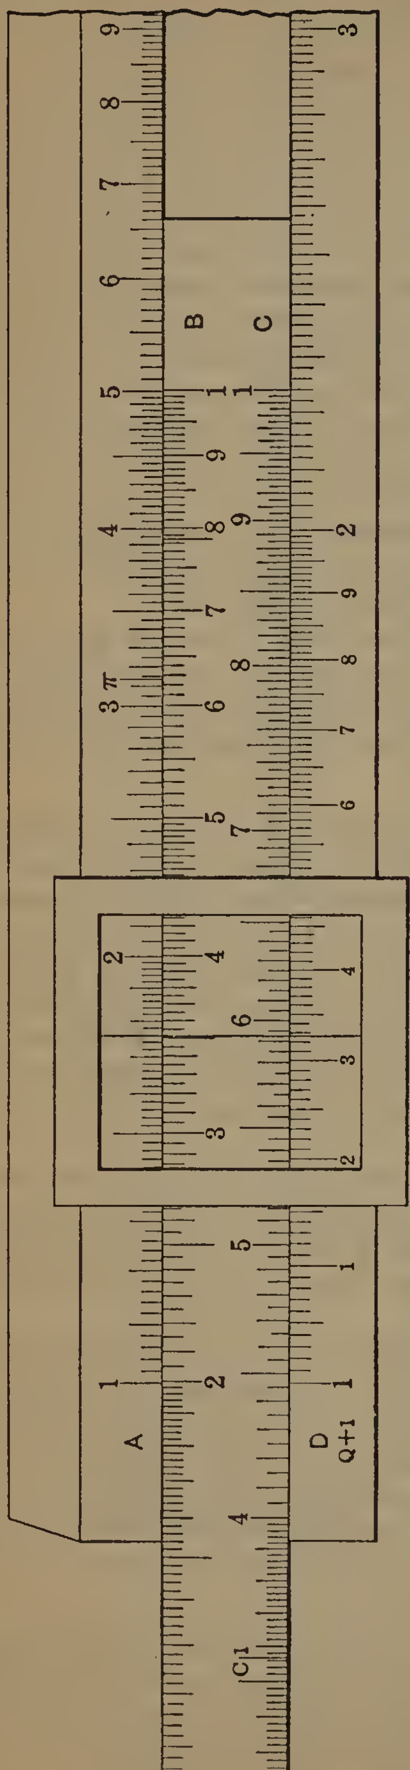

Fig. 5

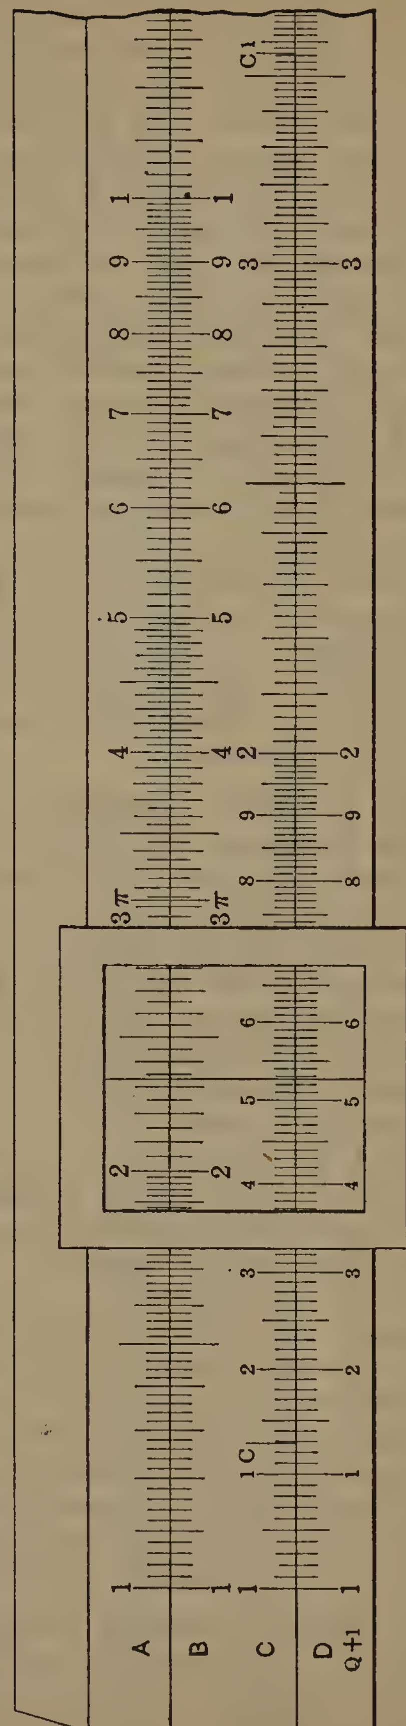

Fig. 6

the number of figures in the divisor and the number of figures in the dividend; but, if the slide projects to the right, the number of ciphers is 1 less than this difference.

Example: — Let the quotient of 176 ÷ 625 be required. Setting the runner and the slide as already explained, the result is found to be 282, with the slide projecting to the left. Then, the number of ciphers between the decimal point and the first figure must be $3 - 3 = 0$, since the divisor and the dividend each contain three figures; that is, the first figure immediately follows the decimal point, and the result is 0.282.

Division of Decimals. — The division of decimals and mixed numbers by means of the slide-rule does not differ in principle from the division of whole numbers. The only difficulty that arises is that of locating the decimal point in the quotient. As the adding of ciphers to the right of a decimal number does not affect its value — that is, 0.2 = 0.20 = 0.200, and so on — the following rule may be formulated:

Rule: — If the problem requires the division of decimals, add ciphers to either the dividend or the divisor until both have the same number of decimal places. Then ignore the decimal points in the new numbers thus obtained, converting them into whole numbers, perform the division as already explained, and locate the decimal point by the proper rule as given in connection with the division of whole numbers.

Example: — As an illustration of the method to be followed, let the quotient of 0.236 ÷ 926 be required. The divisor, 926, may be written 926.000 without changing its value, and the problem then becomes 0.236 ÷ 926.000; or, dropping the decimal points, and treating both as whole numbers, the problem is 236 ÷ 926,000. The runner and slide are set as explained for whole numbers. The slide projects to the left and the quotient on the D scale is 255. There are six figures in the divisor and three in the dividend; hence, the number of ciphers intervening between the decimal point and the first figure is $6 - 3 = 3$. The result, therefore, must be 0.000255.

Squares of Numbers. — The squares and square roots of numbers can readily be found by using the slide-rule. The A and D scales only are used in finding the square of a number. Set the runner so that the hair-line stands over the number on the D scale and the square of that number will be found on the A scale under the hair-line.

Example: — Find the square of 152.7. Set the runner, as shown in Fig. 6, so that the hair-line is over 1527 on the D scale, and under the hair-line on the A scale will be found 233. The number of whole-number places and decimal places in the square can easily be found. If the result is read from the left-hand A scale, the square contains one less than twice as many figures as there are in the original number; whereas, if it is read from the right-hand A scale, the square contains twice as many figures as the original number; and if there is a decimal, there will be twice as many places as in the original number. In the above problem, the original number contains four figures and the result is found on the left-hand A scale; hence, the number of figures in the square is $(2 \times 4) - 1 = 7$. There must also be $2 \times 1 = 2$ decimal places in the final result. Therefore, adding ciphers to 233 to make seven figures and then pointing off two decimal places, the required square is found to be 23,300.00, or 23,300.

Square Root. — The square root of a number is found by reversing the process of finding the square; that is, the number is located on the A scale and the root is found directly below, on the D scale, the hair-line being used to make the readings accurately. If the number is a whole number or a mixed number and contains an *odd* number of figures in the whole-number part, or if it is wholly a decimal and has an *odd* number of ciphers directly following the decimal point, the left-hand A

scale must be used; in all other cases, the right-hand A scale is used. Let N represent the number of figures in the whole-number part, N' the number of ciphers directly following the decimal point, in the root, and n the same numbers in the original number. Then, if the left-hand A scale is used, $N = \frac{n+1}{2}$, and $N' = \frac{n-1}{2}$. If the right-hand A scale is used, $N = N' = \frac{n}{2}$.

The finding of a square root is illustrated in Fig. 6.

Example: — Let the square root of 2.33 be required. As there is an odd number of figures in the whole-number part, the left-hand A scale is used, and below, on the D scale, 1527 is read. With the left-hand A scale in use, $N = \frac{n+1}{2} = \frac{1+1}{2} = 1$; hence, the square root is 1.527.

It is very probable that the number of figures preceding the decimal point, or the number of ciphers following the decimal point, in a square root can be determined more easily and quickly by inspection than by the foregoing rules, because by pointing off the given number into periods of two figures each, as taught in arithmetic, the desired information as to the location of the decimal point in the root can be seen at a glance. It is abso utely necessary, however, to use some form of rule, such as that given, to determine whether the left-hand or the right-hand A scale is to be used.

Cubes of Numbers. — Finding the cube of a number requires the use of all four scales. The index of the C scale is set to the given number on the D scale and, opposite the same number on the *left-hand B* scale, the cube is read from the A scale. Three cases may arise, as follows:

Case I. — The slide may project to the left and the cube be found on the left-hand A scale.

Case II. — The slide may project to the right and the cube be found on the right-hand A scale.

Case III. — The slide may project to the right and the cube be found on the left-hand A scale.

If the number contains a decimal, ignore the decima point for the time being and treat it as a whole number. Let N represent the number of figures in the cube and n the number of figures in the given number. Then:

$$N = 3n, \text{ for Case I;}$$
$$N = 3n - 1, \text{ for Case II;}$$
$$N = 3n - 2, \text{ for Case III.}$$

After the total number of figures has been found by one of these rules, point off three times as many places as there are decimal places in the given number, and the result will be the required cube of the given number.

Example: — To illustrate, suppose that 36.8^3 is to be found. Treat it as a whole number, 368, and set the left-hand index of the C scale to 368 on the D scale, as in Fig. 7. Then, opposite 368 on the left-hand B scale will be found 5 on the A scale. As this setting falls under Case II, $N = (3 \times 3) - 1 = 8$; hence, the reading is 50,000,000. There is one decimal place in the given number, so that three places must be pointed off in the result, giving 50,000.000, or simply 50,000, as the required cube.

The cube can be found quite as readily by multiplying the number together three times; that is, $36.8^3 = 36.8 \times 36.8 \times 36.8$. This continued multiplication can be performed as previously described, and the position of the decimal point be determined by the rules given in that connection. This method will doubtless be found easier to remember than the one outlined above, involving three cases with as many different rules.

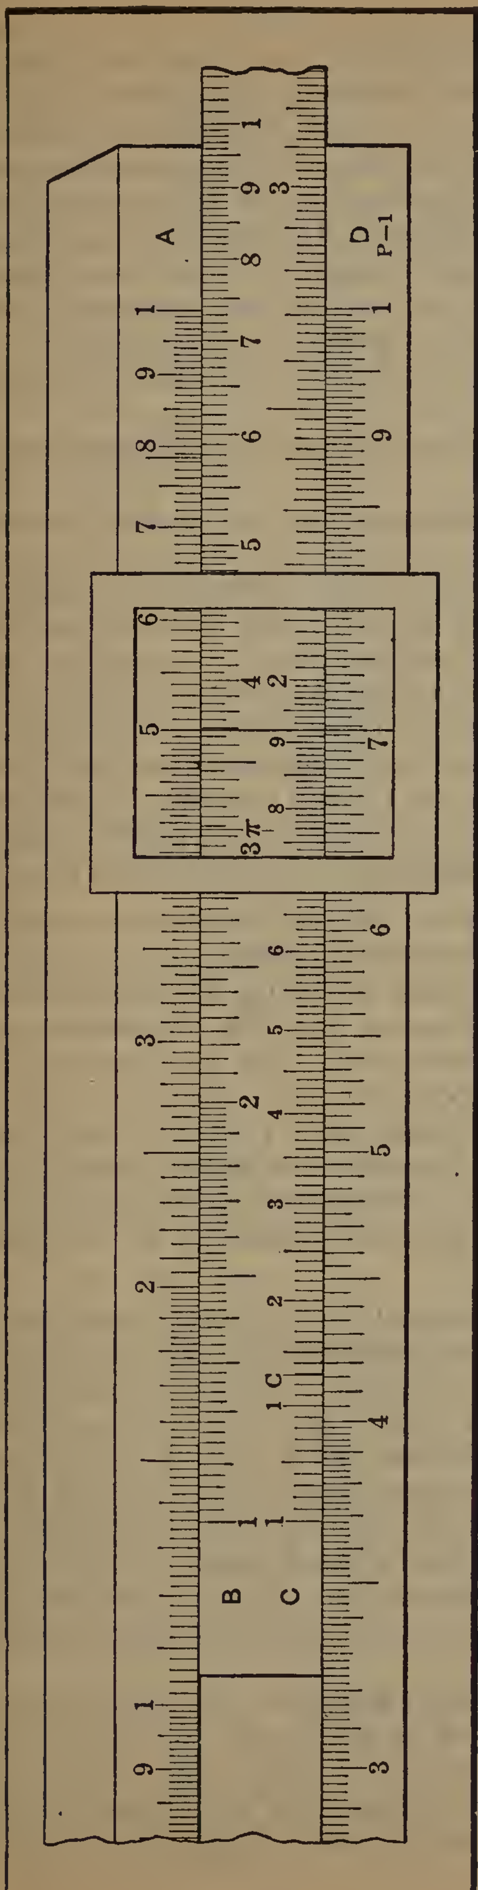

Fig. 7

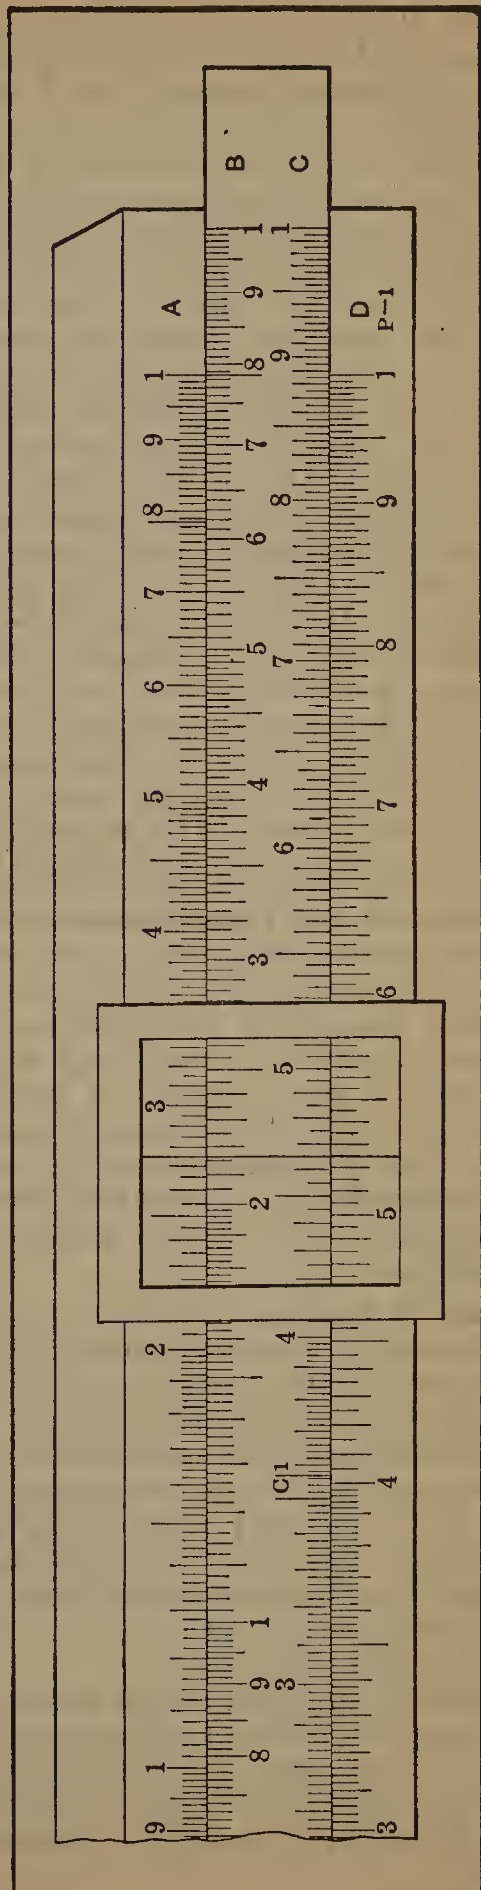

Fig. 8

Cube Root. — The operation of finding the cube root is the reverse of finding the cube, and the method of determining the number of figures in the root, preceding or following the decimal point, is the same as that used in arithmetic; that is, the number is pointed off into periods of three figures each, beginning at the decimal point, and the root then contains one figure for each period or part of a period. If the number contains a decimal, add ciphers to the right of it, if necessary, so that the number of figures in the decimal part will be exactly divisible by 3, without a remainder. The scales and indexes to be used in finding the cube root depend upon the number of figures in the first period at the left, not counting ciphers when they *immediately* follow the decimal point. The rules to be followed are:

Case I. — If there are three figures in the first period, use the left-hand A scale and the right-hand index of the C scale.

Case II. — If there are two figures in the first period, use the right-hand A scale and the left-hand index of the C scale.

Case III. — If there is one figure in the first period, use the left-hand A scale and the left-hand index of the C scale.

Example: — Find the cube root of 0.05. Add ciphers to make three figures, giving 0.050, thus forming one period of three figures. This indicates that the first figure of the root immediately follows the decimal point. As there are two figures, 50, in the first period, "050," the right-hand A scale and the left-hand index of the C scale are used. Set the runner so that the hair-line is across 5 on the right-hand A scale, as in Fig. 7. Then move the slide until the reading on the B scale under the hair-line is exactly equal to that on the D scale opposite the left-hand index of the C scale. This reading on the D scale, 368, is the result required. The first figure of the root must follow the decimal point; therefore, the root is 0.368.

Diameters and Circumferences of Circles. — The ratio of the circumference of a circle to the diameter is $3.1416 = \pi$, and this value is marked by an extra line on the A and B scales, on many rules. It is used in finding the circumference from the diameter by multiplication, or the diameter from the circumference by division. In either instance, the A and B scales are used. The left-hand index of the B scale is set to π on the A scale, and opposite the given diameter on the B scale is read the circumference on the A scale; or, the value π on the B scale is set to the given circumference on the A scale, and opposite the index of the B scale the required diameter is read from the A scale. This multiplication or division is performed in exactly the same way as in using the C and D scales for the same kind of operation.

Areas of Circles. — The area of a circle is equal to 0.7854 times the square of the diameter; consequently, the value 0.7854 is marked by an extra line on the right-hand A and B scales on many rules. To find the area of a circle, having given the diameter, set the line 0.7854 of the B scale to either the left-hand or the right-hand index of the A scale and read the area from the B scale, above the given diameter on the D scale, the hair-line on the runner being used to transfer from D to B. If the area is given, set the slide as before, and read the required diameter from the D scale directly below the given area on the B scale. If the number of figures preceding the decimal point, or the number of ciphers immediately following the decimal point, in the area, is odd, use the left-hand B scale; otherwise, use the right-hand B scale.

Example: — Find the area of a circle $5\frac{1}{4}$ inches in diameter. Set the line marking 0.7854 on the B scale to the right-hand index of the A scale, as in Fig. 8, and above 5.25 on the D scale will be found 21.6 on the B scale; hence, the area is 21.6 square inches. The same setting, taken in reverse order, can be used to illustrate the method of finding the diameter of a circle the area of which is 21.6 square inches.

LOGARITHMS

The object of logarithms is to facilitate and shorten calculations involving multiplication, division, the extraction of roots and the obtaining of powers of numbers. A logarithm consists of two parts, a whole number and a decimal. The whole number, which may be either a positive or negative number, or zero, is called the *characteristic;* the decimal is called the *mantissa.* As a rule, the decimal or mantissa only is given in tables of logarithms. The characteristic is prefixed to the mantissa according to the following rules:

For 1 and for all numbers greater than 1, the characteristic is one less than the number of places to the left of the decimal point in the given number. For example, the characteristic of the logarithm of 237 is 2, and of 2536.5 is 3.

For numbers smaller than 1, that is for numbers wholly decimal, the characteristic is negative and its numerical value is one more than the number of ciphers between the decimal point and the first decimal which is not a cipher. For example, the characteristic of the logarithm of 0.036 is (− 2), and the characteristic of the logarithm of 0.0006 is (− 4). Instead of writing the minus sign (−) in front of the figure, as (− 2), it is frequently written over the figure, thus: ($\bar{2}$). This method

N.	L.	0	1	2	3	4	5	6	7	8	9	P. P.
400	60	206	217	228	239	249	260	271	282	293	304	
401		314	325	336	347	358	369	379	390	401	412	
402		423	433	444	455	466	477	487	498	509	520	
403		531	541	552	563	574	584	595	606	617	627	
404		638	649	660	670	681	692	703	713	724	735	

Fig. 1

is used because the minus sign refers only to the characteristic and not to the mantissa, which is always positive.

The logarithmic tables in the following give, in the body of the tables, the mantissa of the logarithms of numbers from 1 to 10,000. When finding the mantissa, the decimal point in a number is disregarded. The mantissa of the logarithms of 2716, 271.6, 27.16, 2.716, or 0.02716, for example, is the same. The tables give directly the mantissa of logarithms of numbers with four figures or less; the logarithms for numbers with more than four figures can be approximated.

To find the logarithm of a number from the tables, locate the first three figures of the number in the left-hand column, and then find the fourth figure at the top of the columns of the page. Then follow the column down from this last figure until opposite the three first figures in the left-hand column. The figure thus found in the body of the table is the mantissa of the logarithm. If the number of which the logarithm is required does not contain four figures, annex ciphers to the right so as to obtain four figures. If the mantissa of the logarithm of 6 is required, for example, find the mantissa for 6000.

Example: — Find the logarithm of 4032. Locate 403 in the left-hand column of the logarithmic tables, then follow downward the column headed "2" at the top of the page, and find the required mantissa opposite 403. The mantissa is .60552 the "group" figures 60 being found in the column under "L" and prefixed to the figures 552 found directly in the column under "2." The characteristic of the logarithm being 3, log 4032 = 3.60552. (See Fig. 1.)

All the mantissas, or the numbers in the tables, are decimals, and the decimal point has, therefore, been omitted in the tables, since no confusion could arise from this; but it should always be put before the figures of the mantissa as soon as taken from the table.

In the tables it will be found that, in some cases, the figures are preceded by the sign (*). The sign (*) indicates that the two figures to be prefixed are those given in the next line below that in which the last three figures are read. For example the logarithm of 5018 is 3.70053, the two figures to be prefixed being 70 and not 69 as would ordinarily be the case. (See Fig. 2.)

Finding a Number the Logarithm of which is Given.—When a logarithm is given and it is required to find the corresponding number, find the first two figures of the mantissa in the column headed "L" in the tables; then find in the group of mantissas, all having the same first two figures, the remaining three figures. These may appear in any of the columns headed "0" to "9". The number heading the column in which the last three figures of the mantissa are found is the last figure in the number sought, and the number in the left-hand column, headed "N," in line with the last three figures of the mantissa, gives the three first figures in the number sought. When the actual figures in the number sought have been deter-

N.	L.	0	1	2	3	4	5	6	7	8	9	P. P.
500	69	897	906	914	923	932	940	949	958	966	975	
501		984	992	*001	*010	*018	*027	*036	*044	*053	*062	
502	70	070	079	088	096	105	114	122	131	140	148

504		243	252	260	269	278	286	295	303	312	321	

Fig. 2

mined, locate the decimal point according to the rules given for the characteristic of logarithms. If the characteristic is greater than 3, add ciphers. For example, if the figures corresponding to a given mantissa are 3765 and the characteristic is 5, then the number sought has 6 figures to the left of the decimal point, and is 376,500. If the characteristic had been $\bar{3}$, then the number sought would, in this case, have been 0.003765. If the mantissa is not exactly obtainable in the tables, find the mantissa in the table which is the nearest to the one given and determine the number corresponding to this. In most cases, this gives results accurate enough. By interpolation, as will be explained later, more accurate results can be obtained.

If the three last figures of the mantissa, as found in the table, are preceded by a (*), it indicates that these three figures belong to the group preceded by the two figures in the "L" column in the line next below.

Example: — Find the number the logarithm of which is 2.70053.

First find the two figures of the mantissa (70) in the column headed "L" in the tables. Then find the remaining three figures (053) in the mantissas which all have 70 for their first two figures. The (*) in front of the figure *053 in the line next above that in which 70 is found indicates that these figures belong to the group preceded by 70. Therefore, the number corresponding to the logarithm 2.70053 is 501.8. (See Fig. 2.)

Multiplication by Logarithms.—If two or more numbers are to be multiplied together, find the logarithms of the numbers to be multiplied, and add these logarithms. The sum is the logarithm of the product, and the number corresponding to this logarithm, as found from the logarithmic tables, is the required product.

Example: — Find the product of $2831 \times 2.692 \times 29.69 \times 19.4$.

This calculation is carried out by means of logarithms as follows:

$$\begin{array}{ll} \log 2831. & = 3.45194 \\ \log 2.692 & = 0.43008 \\ \log 29.69 & = 1.47261 \\ \log 19.4 & = 1.28780 \\ \hline & 6.64243 \end{array}$$

The product, as found from the tables, with ciphers added, then is 4,390,000.

Division by Logarithms. — When dividing one number by another, subtract the logarithm of the divisor from the logarithm of the dividend; the remainder is the logarithm of the quotient. For example, to find the quotient of $7658 \div 935.3$, find log 7658 and subtract from it log 935.3; the remainder is the logarithm of the quotient.

A modified method, especially useful when the dividend and divisor are composed of several factors, is to use the negative value of the logarithms of all the numbers or factors of the divisor. These negative values can then be *added* to the logarithms of the factors composing the dividend. As the mantissa must always remain positive, however, in order to permit direct addition, the negative value of the logarithm cannot be obtained by simply placing a minus sign before it. Instead it is obtained in the following manner:

If the characteristic is positive, add 1 to its numerical value and place a minus sign over it. To obtain the mantissa, subtract the given mantissa from 1.00000.

Example: — The logarithm of $950 = 2.97772$. Find $(-\log 950)$. According to the rule, the characteristic will be $\bar{3}$. The mantissa will be $1.00000 - .97772 = .02228$. Hence, $(-\log 950) = \bar{3}.02228$.

If the characteristic of the logarithm is negative, subtract 1 from its numerical value and make it positive. The mantissa is obtained by the same rule as given above. For example, the logarithm of $0.003 = \bar{3}.47712$; hence, $(-\log 0.003) = 2.52288$. The following example shows the usefulness of this method in an actual calculation:

$$\frac{0.0272 \times 27.1 \times 12.6}{2.371 \times 0.007}$$

$$\begin{array}{ll} \log 0.0272 & = \bar{2}.43457 \\ \log 27.1 & = 1.43297 \\ \log 12.6 & = 1.10037 \\ -\log 2.371 & = \bar{1}.62507 \\ -\log 0.007 & = 2.15490 \\ \hline & 2.74788 \end{array}$$

The result, then, is 559.6.

Obtaining the Powers of Numbers. — A number may be raised to any power by simply multiplying the logarithm of the number by the exponent of the number. The product gives the logarithm of the value of the power.

Example 1. — Find the value of 6.51^3.

$$\log 6.51 = 0.81358$$

$$3 \times 0.81358 = 2.44074$$

The logarithm 2.44074 is then the logarithm of 6.51^3. Hence 6.51^3 equals the number corresponding to this logarithm, as found from the tables, or $6.51^3 = 275.9$.

Example 2. — Find the value of $12^{1.29}$.

$$\log 12 = 1.07918$$

$$1.29 \times 1.07918 = 1.39214$$

Hence, $12^{1.29} = 24.67$.

The multiplication 1.29×1.07918 is carried out in the usual arithmetical way. The example above is one of a type which cannot be solved by any means except by the use of logarithms.

One difficulty is met with when raising a number less than 1 to a given power. The logarithm is then composed of a negative term, the characteristic, and a positive term, the mantissa. For example: Find the value 0.31^5. The logarithm of $0.31 = \bar{1}.49136$. In this case, multiply, separately, the characteristic and the mantissa by the exponent, as shown below. Then add the products.

$$\log 0.31 = \bar{1}.49136$$

Multiplying characteristic and mantissa separately by 5 we have:

$$5 \times \bar{1} = \bar{5}$$

$$5 \times 0.49136 = 2.45680$$

$$\log 0.31^5 = \bar{3}.45680$$

Hence, $0.31^5 = 0.002863$.

Extracting Roots by Logarithms. — Roots of numbers, as for example $\sqrt[5]{37}$, can easily be extracted by means of logarithms. The small (5) in the radical ($\sqrt{\ }$) of the root-sign is called the index of the root. Any root of a number may be found by dividing its logarithm by the index of the root; the quotient is the logarithm of the root.

Example 1. — Find $\sqrt[3]{276}$.

$$\log 276 = 2.44091$$

$$2.44091 \div 3 = 0.81364$$

Hence $\log \sqrt[3]{276} = 0.81364$, and $\sqrt[3]{276} = 6.511$.

Example 2. — Find $\sqrt[3]{0.67}$.

$$\log 0.67 = \bar{1}.82607$$

In this case it is not possible to divide directly, because there is a negative characteristic and a positive mantissa. Proceed as follows: Add numerically as many *negative* units or parts of units to the characteristic as is necessary to make it evenly contain the index of the root. Then add the *same* number of *positive* units or parts of units to the mantissa. Divide each separately by the index. The quotients give the characteristic and mantissa, respectively, of the logarithm of the root. Proceeding with the example above according to this rule, we have:

$$\bar{1} + \bar{2} = \bar{3}; \quad \bar{3} \div 3 = \bar{1}.$$

$$.82607 + 2 = 2.82607; \quad 2.82607 \div 3 = .94202.$$

Hence, $\log \sqrt[3]{0.67} = \bar{1}.94202$, and $\sqrt[3]{0.67} = 0.875$.

Example 3. — Find $\sqrt[1.7]{0.2}$.

$$\log 0.2 = \bar{1}.30103.$$

If we add (-0.7) to the characteristic of the logarithm found, it will be evenly divisible by the index of the root.

Hence:

$$\bar{1} + (-0.7) = -1.7; \quad -1.7 \div 1.7 = \bar{1}.$$

$$.30103 + 0.7 = 1.00103; \quad 1.00103 \div 1.7 = .58884.$$

Hence, $\log \sqrt[1.7]{0.2} = \bar{1}.58884$, and $\sqrt[1.7]{0.2} = 0.388$.

When exponents or indices are given in common fractions, it is usually best to change them to decimal fractions before proceeding further with the problem.

Interpolation. — If the number for which the logarithm is required consists of five figures, it is possible by means of the small tables in the right-hand column of the logarithmic tables, headed "P.P." (proportional parts), to obtain the logarithm more accurately than by taking the nearest value for four figures. The logarithm of 1524.2, for example, is found as follows:

First find the difference between the nearest larger and the nearest smaller logarithms in the table. Log 1524 = 3.18298 and log 1525 = 3.18327. (See Fig. 3.) The difference is 0.00029. Then in the small table headed "29" in the right-hand

N.	L.	0	1	2	3	4	5	6	7	8	9	P. P.		
150	17	609	638	667	696	725	754	782	811	840	869			
151		898	926	955	984	*013	*041	*070	*099	*127	*156		29	28
152	18	184	213	241	270	298	327	355	384	412	441	1	2,9	2,8

154		752	780	808	837	865	893	921	949	977	*005	3	8,7	8,4

Fig. 3

column, find the figure opposite 2 (2 being the last or fifth figure in the given number). This figure is 5.8. Add this to the mantissa of the smaller of the two logarithms already found, disregarding the decimal point in the mantissa, and considering it, for the while being, as a whole number. Then, 18298 + 5.8 = 18303.8, or approximately, 18304. This is the mantissa of the logarithm of 1524.2 and the complete logarithm is 3.18304.

To find a number more accurately than to four figures, when the mantissa cannot be found exactly in the tables, find the mantissa which is nearest to, but less than, the given mantissa. Subtract this mantissa from the nearest larger mantissa in the tables and find in the right-hand column the small table headed by this difference. Then subtract the nearest smaller mantissa from the given logarithm and find the exact or approximate difference in the "proportional part" table. The corresponding figure in the left-hand column of the "proportional part" table is the fifth figure in the number sought, the other four figures being those corresponding to the logarithm next smaller than the given logarithm. In accordance with this rule, the number corresponding to the logarithm 4.46262 is found to be 29,015.

Hyperbolic Logarithms. — In many calculations, notably those involving calculations of the mean effective pressure of steam in engine cylinders, use is made of logarithms termed *hyperbolic*, *Napierian*, or *natural*; the preferable name, and that most commonly used in the United States, is hyperbolic logarithms. The hyperbolic logarithms are usually designated "hyp. log." Sometimes the hyperbolic logarithm is also designated "$\log_e$" and "nat. log." Tables are given in the following for hyperbolic logarithms from 1 to 100.

To convert the common logarithms to hyperbolic logarithms, the former should be multiplied by 2.30258. To convert hyperbolic logarithms to common logarithms, multiply by 0.43429. Hyperbolic logarithms find extensive use in higher mathematics.

Mensuration

In the following tables are given the areas of plane figures, together with other formulas relating to their dimensions and properties; the surfaces of solids; and the volumes of solids. The notation used in the formulas is, as far as possible, given in the illustration accompanying them; where this has not been possible, it is given at the beginning of each set of formulas.

 **Square**	A = area. $A = s^2$ $A = \frac{1}{2} d^2$ $s = 0.7071\, d = \sqrt{A}$ $d = 1.414\, s = 1.414 \sqrt{A}$
 **Rectangle**	A = area. $A = ab$ $A = a\sqrt{d^2 - a^2} = b\sqrt{d^2 - b^2}$ $d = \sqrt{a^2 + b^2}$ $a = \sqrt{d^2 - b^2} = A \div b$ $b = \sqrt{d^2 - a^2} = A \div a$
 **Parallelogram**	A = area. $A = ab$ $a = A \div b$ $b = A \div a$ Note that dimension a is measured at right angles to line b.
 **Right-angled Triangle**	A = area. $A = \frac{bc}{2}$ $a = \sqrt{b^2 + c^2}$ $b = \sqrt{a^2 - c^2}$ $c = \sqrt{a^2 - b^2}$
 **Acute-angled Triangle**	A = area. $A = \frac{bh}{2} = \frac{b}{2}\sqrt{a^2 - \left(\frac{a^2 + b^2 - c^2}{2\,b}\right)^2}$ If $S = \frac{1}{2}(a + b + c)$, then $A = \sqrt{S(S-a)(S-b)(S-c)}$

Examples of the Use of the Formulas

Below are given a number of examples showing the use of the formulas on the opposite page. Each section of the page corresponds to the opposite section on the previous page, and the illustration on that page should be referred to. The notation used in the illustrations is also used in the examples given.

Square. — Assume that the side s of a square is 15 inches. Find the area and the length of the diagonal.

$$\text{Area} = A = s^2 = 15^2 = 225 \text{ square inches.}$$

$$\text{Diagonal} = d = 1.414\, s = 1.414 \times 15 = 21.21 \text{ inches.}$$

The area of a square is 625 square inches. Find the length of the side s and the diagonal d.

$$s = \sqrt{A} = \sqrt{625} = 25 \text{ inches.}$$

$$d = 1.414 \sqrt{A} = 1.414 \times 25 = 35.35 \text{ inches.}$$

Rectangle. — The side a of a rectangle is 12 inches, and the area 70.5 square inches. Find the length of the side b, and the diagonal d.

$$b = A \div a = 70.5 \div 12 = 5.875 \text{ inches.}$$

$$d = \sqrt{a^2 + b^2} = \sqrt{12^2 + 5.875^2} = \sqrt{178.516} = 13.361 \text{ inches.}$$

The sides of a rectangle are 30.5 and 11 inches long. Find the area.

$$\text{Area} = a \times b = 30.5 \times 11 = 335.5 \text{ square inches.}$$

Parallelogram. — The base b of a parallelogram is 16 feet. The height a is 5.5 feet. Find the area.

$$\text{Area} = A = a \times b = 5.5 \times 16 = 88 \text{ square feet.}$$

The area of a parallelogram is 12 square inches. The height is 1.5 inch. Find the length of the base b.

$$b = A \div a = 12 \div 1.5 = 8 \text{ inches.}$$

Right-angled Triangle. — The sides b and c in a right-angled triangle are 6 and 8 inches. Find side a and the area.

$$a = \sqrt{b^2 + c^2} = \sqrt{6^2 + 8^2} = \sqrt{36 + 64} = \sqrt{100} = 10 \text{ inches.}$$

$$A = \frac{b \times c}{2} = \frac{6 \times 8}{2} = \frac{48}{2} = 24 \text{ square inches.}$$

If $a = 10$ and $b = 6$, had been known, but not c, the latter would have been found as follows:

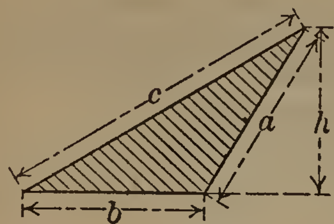
$$c = \sqrt{a^2 - b^2} = \sqrt{10^2 - 6^2} = \sqrt{100 - 36} = \sqrt{64} = 8 \text{ inches.}$$

Acute-angled Triangle. — If $a = 10$, $b = 9$, and $c = 8$ inches, what is the area of the triangle?

$$A = \frac{b}{2}\sqrt{a^2 - \left(\frac{a^2 + b^2 - c^2}{2\,b}\right)^2} = \frac{9}{2}\sqrt{10^2 - \left(\frac{10^2 + 9^2 - 8^2}{2 \times 9}\right)^2} = 4.5\sqrt{100 - \left(\frac{117}{18}\right)^2}$$

$$= 4.5\sqrt{100 - 42.25} = 4.5\sqrt{57.75} = 4.5 \times 7.60 = 34.20 \text{ square inches.}$$

Mensuration



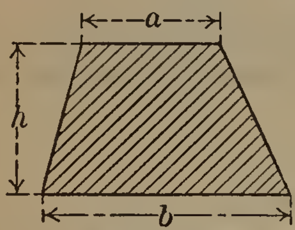
Obtuse-angled Triangle

A = area.

$$A = \frac{bh}{2} = \frac{b}{2}\sqrt{a^2 - \left(\frac{c^2 - a^2 - b^2}{2b}\right)^2}$$

If $S = \frac{1}{2}(a + b + c)$, then

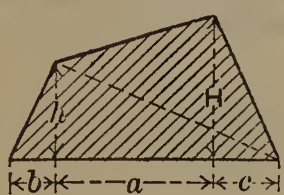
$$A = \sqrt{S(S-a)(S-b)(S-c)}$$



Trapezoid

A = area.

$$A = \frac{(a+b)\,h}{2}$$



Trapezium

A = area.

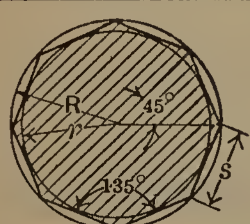
$$A = \frac{(H+h)\,a + bh + cH}{2}$$

A trapezium can also be divided into two triangles as indicated by the dotted line. The area of each of these triangles is computed, and the results added to find the area of the trapezium.

Regular Hexagon

A = area;
R = radius of circumscribed circle;
r = radius of inscribed circle.

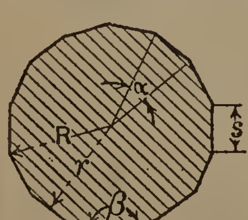
$A = 2.598\,s^2 = 2.598\,R^2 = 3.464\,r^2$
$R = s = 1.155\,r$
$r = 0.866\,s = 0.866\,R$
$s = R = 1.155\,r$



Regular Octagon

A = area;
R = radius of circumscribed circle;
r = radius of inscribed circle.

$A = 4.828\,s^2 = 2.828\,R^2 = 3.314\,r^2$
$R = 1.307\,s = 1.082\,r$
$r = 1.207\,s = 0.924\,R$
$s = 0.765\,R = 0.828\,r$



Regular Polygon

A = area; n = number of sides.
$\alpha = 360° \div n$ $\beta = 180° - \alpha$

$$A = \frac{nsr}{2} = \frac{ns}{2}\sqrt{R^2 - \frac{s^2}{4}}$$

$$R = \sqrt{r^2 + \frac{s^2}{4}};\quad r = \sqrt{R^2 - \frac{s^2}{4}};\quad s = 2\sqrt{R^2 - r^2}$$

Examples of the Use of the Formulas

Obtuse-angled Triangle. — The side $a = 5$, side $b = 4$, and side $c = 8$ inches. Find the area.

$$S = \tfrac{1}{2}(a + b + c) = \tfrac{1}{2}(5 + 4 + 8) = \tfrac{1}{2} \times 17 = 8.5$$

$$A = \sqrt{S(S-a)(S-b)(S-c)} = \sqrt{8.5\,(8.5-5)\,(8.5-4)\,(8.5-8)}$$

$$= \sqrt{8.5 \times 3.5 \times 4.5 \times 0.5} = \sqrt{66.937} = 8.18 \text{ square inches.}$$

Trapezoid. — Side $a = 23$ feet, side $b = 32$ feet, and height $h = 12$ feet. Find the area.

$$A = \frac{(a+b)\,h}{2} = \frac{(23+32)\,12}{2} = \frac{55 \times 12}{2} = \frac{660}{2} = 330 \text{ square feet.}$$

Trapezium. — Let $a = 10$, $b = 2$, $c = 3$, $h = 8$, and $H = 12$ inches. Find the area.

$$A = \frac{(H+h)\,a + bh + cH}{2} = \frac{(12+8)\,10 + 2 \times 8 + 3 \times 12}{2}$$

$$= \frac{20 \times 10 + 16 + 36}{2} = \frac{252}{2} = 126 \text{ square inches.}$$

Regular Hexagon. — The side s of a regular hexagon is 4 inches. Find the area and the radius r of the inscribed circle.

$$A = 2.598\,s^2 = 2.598 \times 4^2 = 2.598 \times 16 = 41.568 \text{ square inches.}$$

$$r = 0.866\,s = 0.866 \times 4 = 3.464 \text{ inches.}$$

What is the length of the side of a hexagon that is described about a circle of 5 inches radius? — Here $r = 5$. Hence,

$$s = 1.155\,r = 1.155 \times 5 = 5.775 \text{ inches.}$$

Regular Octagon. — Find the area and the length of the side of an octagon that is inscribed in a circle of 12 inches diameter.

Diameter of circumscribed circle = 12 inches; hence, $R = 6$ inches.

$$A = 2.828\,R^2 = 2.828 \times 6^2 = 2.828 \times 36 = 101.81 \text{ square inches.}$$

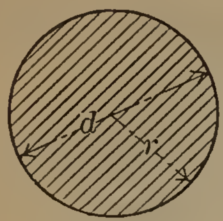
$$s = 0.765\,R = 0.765 \times 6 = 4.590 \text{ inches.}$$

Regular Polygon. — Find the area of a polygon having 12 sides, inscribed in a circle of 8 inches radius. The length of the side s is 4.141 inches.

$$A = \frac{ns}{2}\sqrt{R^2 - \frac{s^2}{4}} = \frac{12 \times 4.141}{2}\sqrt{8^2 - \frac{4.141^2}{4}} = 24.846\sqrt{59.713}$$

$$= 24.846 \times 7.727 = 191.98 \text{ square inches.}$$

Mensuration



Circle

A = area; C = circumference.

$$A = \pi r^2 = 3.1416\, r^2 = 0.7854\, d^2$$

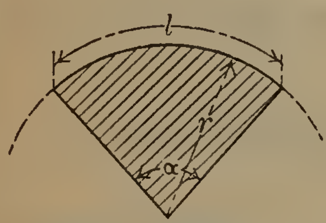
$$C = 2\pi r = 6.2832\, r = 3.1416\, d$$

$$r = C \div 6.2832 = \sqrt{A \div 3.1416} = 0.564\sqrt{A}$$

$$d = C \div 3.1416 = \sqrt{A \div 0.7854} = 1.128\sqrt{A}$$

Length of arc for center-angle of $1° = 0.008727\, d$

Length of arc for center-angle of $n° = 0.008727\, nd$



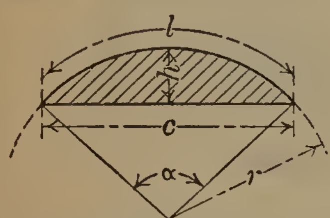
Circular Sector

A = area; l = length of arc; α = angle, in degrees.

$$l = \frac{r \times \alpha \times 3.1416}{180} = 0.01745\, r\alpha = \frac{2A}{r}$$

$$A = \tfrac{1}{2} rl = 0.008727\, \alpha r^2$$

$$\alpha = \frac{57.296\, l}{r} \qquad r = \frac{2A}{l} = \frac{57.296\, l}{\alpha}$$



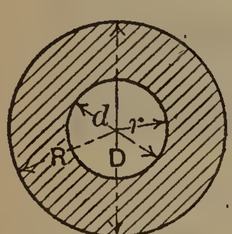
Circular Segment

A = area; l = length of arc; α = angle, in degrees.

$$c = 2\sqrt{h(2r - h)} \qquad A = \tfrac{1}{2}[rl - c(r - h)]$$

$$r = \frac{c^2 + 4h^2}{8h} \qquad l = 0.01745\, r\alpha$$

$$h = r - \tfrac{1}{2}\sqrt{4r^2 - c^2} \qquad \alpha = \frac{57.296\, l}{r}$$



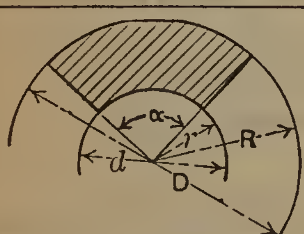
Circular Ring

A = area.

$$A = \pi(R^2 - r^2) = 3.1416\,(R^2 - r^2)$$

$$= 3.1416\,(R + r)(R - r)$$

$$= 0.7854\,(D^2 - d^2) = 0.7854\,(D + d)(D - d)$$

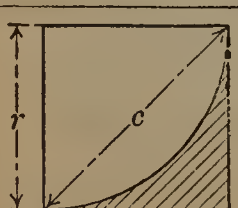


Circular Ring Sector

A = area; α = angle, in degrees.

$$A = \frac{\alpha\pi}{360}(R^2 - r^2) = 0.00873\, \alpha\,(R^2 - r^2)$$

$$= \frac{\alpha\pi}{4 \times 360}(D^2 - d^2) = 0.00218\, \alpha\,(D^2 - d^2)$$



Spandrel or Fillet

A = area.

$$A = r^2 - \frac{\pi r^2}{4} = 0.215\, r^2$$

$$= 0.1075\, c^2$$

Examples of the Use of the Formulas

Circle. — Find the area A and circumference C of a circle with a diameter of 2¾ inches.

$A = 0.7854\,d^2 = 0.7854 \times 2.75^2 = 0.7854 \times 2.75 \times 2.75 = 5.9396$ square inches.

$C = 3.1416\,d = 3.1416 \times 2.75 = 8.6394$ inches.

The area of a circle is 16.8 square inches. Find its diameter.

$$d = 1.128\sqrt{A} = 1.128\sqrt{16.8} = 1.128 \times 4.099 = 4.624 \text{ inches.}$$

Circular Sector. — The radius of a circle is 1½ inch, and angle α of a sector of the circle is 60 degrees. Find the area of the sector and the length of arc l.

$A = 0.008727\,\alpha r^2 = 0.008727 \times 60 \times 1.5^2 = 0.5236 \times 1.5 \times 1.5 = 1.178$ sq. inch.

$l = 0.01745\,r\alpha = 0.01745 \times 1.5 \times 60 = 1.5705$ inch.

Circular Segment. — The radius r of a circular segment is 60 inches and the height h is 8 inches. Find the length of the chord c.

$c = 2\sqrt{h(2r-h)} = 2\sqrt{8 \times (2 \times 60 - 8)} = 2\sqrt{896} = 2 \times 29.93 = 59.86$ inches.

If $c = 16$, and $h = 6$ inches, what is the radius of the circle of which the segment is a part?

$$r = \frac{c^2 + 4h^2}{8h} = \frac{16^2 + 4 \times 6^2}{8 \times 6} = \frac{256 + 144}{48} = \frac{400}{48} = 8\tfrac{1}{3} \text{ inches.}$$

Circular Ring. — Let the outside diameter $D = 12$ inches and the inside diameter $d = 8$ inches. Find area of ring.

$A = 0.7854\,(D^2 - d^2) = 0.7854\,(12^2 - 8^2) = 0.7854\,(144 - 64) = 0.7854 \times 80$
$= 62.83$ square inches.

By the alternative formula:

$A = 0.7854\,(D + d)\,(D - d) = 0.7854\,(12 + 8)\,(12 - 8) = 0.7854 \times 20 \times 4$
$= 62.83$ square inches.

Circular Ring Sector. — Find the area, if the outside radius $R = 5$ inches, the inside radius $r = 2$ inches, and $\alpha = 72$ degrees.

$$A = 0.00873\,\alpha\,(R^2 - r^2) = 0.00873 \times 72\,(5^2 - 2^2)$$
$$= 0.6286\,(25 - 4) = 0.6286 \times 21 = 13.2 \text{ square inches.}$$

Spandrel or Fillet. — Find the area of a spandrel, the radius of which is 0.7 inch.

$$A = 0.215\,r^2 = 0.215 \times 0.7^2 = 0.215 \times 0.7 \times 0.7 = 0.105 \text{ square inch.}$$

If chord c were given as 2.2 inches, what would be the area?

$$A = 0.1075\,c^2 = 0.1075 \times 2.2^2 = 0.1075 \times 4.84 = 0.520 \text{ square inch.}$$

Mensuration

<table>
<tr><td>Ellipse</td><td>A = area; P = perimeter or circumference.
$A = \pi ab = 3.1416\,ab.$
An approximate formula for the perimeter is:
$P = 3.1416\sqrt{2\,(a^2+b^2)}$
A closer approximation is:
$P = 3.1416\sqrt{2\,(a^2+b^2) - \frac{(a-b)^2}{2.2}}$</td></tr>
<tr><td>Hyperbola</td><td>A = area BCD.
$A = \frac{xy}{2} - \frac{ab}{2}\text{ hyp. log}\left(\frac{x}{a}+\frac{y}{b}\right)$</td></tr>
<tr><td>Parabola</td><td>l = length of arc.
$l = \frac{p}{2}\left[\sqrt{\frac{2x}{p}\left(1+\frac{2x}{p}\right)} + \text{hyp. log}\left(\sqrt{\frac{2x}{p}} + \sqrt{1+\frac{2x}{p}}\right)\right]$
When x is small in proportion to y, the following is a close approximation:
$l = y\left[1 + \frac{2}{3}\left(\frac{x}{y}\right)^2 - \frac{2}{5}\left(\frac{x}{y}\right)^4\right]$, or $l = \sqrt{y^2 + \frac{4}{3}x^2}$</td></tr>
<tr><td>Parabola</td><td>A = area.
$A = \frac{2}{3}xy$
(The area is equal to two-thirds of the rectangle which has x for its base and y for its height.)</td></tr>
<tr><td>Segment of Parabola</td><td>A = area.
Area $BFC = A = \frac{2}{3}$ area of parallelogram $BCDE$.
If FG is the height of the segment, measured at right angles to BC, then:
Area of segment $BFC = \frac{2}{3}\,BC \times FG$</td></tr>
<tr><td>Cycloid</td><td>A = area; l = length of cycloid.
$A = 3\pi r^2 = 9.4248\,r^2 = 2.3562\,d^2$
$= 3 \times$ area of generating circle
$l = 8r = 4d$</td></tr>
</table>

Examples of the Use of the Formulas

Ellipse. — The larger or major axis is 8 inches. The smaller or minor axis is 6 inches. Find the area and the approximate circumference. Here, then, $a = 4$, and $b = 3$.

$$A = 3.1416\,ab = 3.1416 \times 4 \times 3 = 37.699 \text{ square inches.}$$

$$P = 3.1416\sqrt{2\,(a^2 + b^2)} = 3.1416 \times \sqrt{2\,(4^2 + 3^2)} = 3.1416 \times \sqrt{2 \times 25}$$
$$= 3.1416\sqrt{50} = 3.1416 \times 7.071 = 22.214 \text{ inches.}$$

Hyperbola. — The half-axes a and b are 3 and 2 inches, respectively. Find area shown shaded in illustration for $x = 8$ and $y = 5$.

Inserting the known values in the formula:

$$A = \frac{8 \times 5}{2} - \frac{3 \times 2}{2} \times \text{hyp. log}\left(\frac{8}{3} + \frac{5}{2}\right) = 20 - 3 \times \text{hyp. log } 5.167$$
$$= 20 - 3 \times 1.6423 = 20 - 4.927 = 15.073 \text{ square inches.}$$

Parabola. — If $x = 2$ and $y = 24$ feet, what is the approximate length l of the parabolic curve?

$$l = y\left[1 + \frac{2}{3}\left(\frac{x}{y}\right)^2 - \frac{2}{5}\left(\frac{x}{y}\right)^4\right] = 24\left[1 + \frac{2}{3}\left(\frac{2}{24}\right)^2 - \frac{2}{5}\left(\frac{2}{24}\right)^4\right]$$
$$= 24\left[1 + \frac{2}{3} \times \frac{1}{144} - \frac{2}{5} \times \frac{1}{20{,}736}\right] = 24 \times 1.0046 = 24.11 \text{ feet.}$$

Parabola. — Let the dimension x in the illustration be 15 inches, and y, 9 inches. Find the area of the shaded portion ot the parabola.

$$A = \tfrac{2}{3} \times xy = \tfrac{2}{3} \times 15 \times 9 = 10 \times 9 = 90 \text{ square inches.}$$

Segment of Parabola. — The length of the chord $BC = 19.5$ inches. The distance between lines BC and DE, measured at right angles to BC, is 2.25 inches. This is the height of the segment. Find the area.

$$\text{Area} = A = \tfrac{2}{3}\,BC \times FG = \tfrac{2}{3} \times 19.5 \times 2.25 = 29.25 \text{ square inches.}$$

Cycloid. — The diameter of the generating circle of a cycloid is 6 inches. Find the length l of the cycloidal curve, and the area enclosed between the curve and the base line.

$$l = 4\,d = 4 \times 6 = 24 \text{ inches.}$$
$$A = 2.3562\,d^2 = 2.3562 \times 6^2 = 2.3562 \times 36 = 84.82 \text{ square inches.}$$

Volumes of Solids

 **Cube**	V = volume. $V = s^3$ $s = \sqrt[3]{V}$
 **Square Prism**	V = volume. $V = abc$ $a = \dfrac{V}{bc}$ $\quad b = \dfrac{V}{ac}$ $\quad c = \dfrac{V}{ab}$
 **Prism**	V = volume; A = area of end surface. $V = h \times A$ The area A of the end surface is found by the formulas for areas of plane figures on the preceding pages. Height h must be measured perpendicular to end surface.
 **Pyramid**	V = volume. $V = \frac{1}{3} h \times$ area of base. If the base is a regular polygon with n sides, and s = length of side, r = radius of inscribed circle, and R = radius of circumscribed circle, then: $V = \dfrac{nsrh}{6} = \dfrac{nsh}{6}\sqrt{R^2 - \dfrac{s^2}{4}}$
 **Frustum of Pyramid**	V = volume. $V = \dfrac{h}{3}(A_1 + A_2 + \sqrt{A_1 \times A_2})$
 **Wedge**	V = volume. $V = \dfrac{(2a + c)\,bh}{6}$

Examples of the Use of the Formulas

Cube. — The side of a cube equals 9.5 inches. Find its volume.

$$\text{Volume} = V = s^3 = 9.5^3 = 9.5 \times 9.5 \times 9.5 = 857.375 \text{ cubic inches.}$$

The volume of a cube is 231 cubic inches. What is the length of the side?

$$s = \sqrt[3]{V} = \sqrt[3]{231} = 6.136 \text{ inches.}$$

Square Prism. — In a square prism, $a = 6$, $b = 5$, $c = 4$. Find the volume.

$$V = a \times b \times c = 6 \times 5 \times 4 = 120 \text{ cubic inches.}$$

How high should a box be made to contain 25 cubic feet, if it is 4 feet long and $2\frac{1}{2}$ feet wide? Here, $a = 4$, $c = 2.5$, and $V = 25$. Then,

$$b = \text{depth} = \frac{V}{ac} = \frac{25}{4 \times 2.5} = \frac{25}{10} = 2.5 \text{ feet.}$$

Prism. — A prism having for its base a regular hexagon with a side s of 3 inches, is 10 inches high. Find the volume.

$$\text{Area of hexagon} = A = 2.598\,s^2 = 2.598 \times 9 = 23.382 \text{ square inches.}$$

$$\text{Volume of prism} = h \times A = 10 \times 23.382 = 233.82 \text{ cubic inches.}$$

Pyramid. —A pyramid, having a height of 9 feet, has a base formed by a rectangle, the sides of which are 2 and 3 feet, respectively. Find the volume.

$$\text{Area of base} = 2 \times 3 = 6 \text{ square feet;} \quad h = 9 \text{ feet.}$$

$$\text{Volume} = V = \tfrac{1}{3}\,h \times \text{area of base} = \tfrac{1}{3} \times 9 \times 6 = 18 \text{ cubic feet.}$$

Frustum of Pyramid. — The pyramid in the previous example is cut off $4\frac{1}{2}$ feet from the base, the upper part being removed. The sides of the rectangle forming the top surface of the frustum are, then, 1 and $1\frac{1}{2}$ foot long, respectively. Find the volume of the frustum.

$$\text{Area of top} = A_1 = 1 \times 1\tfrac{1}{2} = 1\tfrac{1}{2} \text{ sq. ft.} \quad \text{Area of base} = A_2 = 2 \times 3 = 6 \text{ sq. ft.}$$

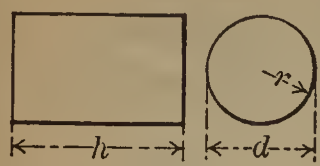
$$V = \frac{4.5}{3}\left(1.5 + 6 + \sqrt{1.5 \times 6}\right) = 1.5\left(7.5 + \sqrt{9}\right) = 1.5 \times 10.5 = 15.75 \text{ cubic feet.}$$

Wedge. — Let $a = 4$ inches, $b = 3$ inches, and $c = 5$ inches. The height $h = 4.5$ inches. Find the volume.

$$V = \frac{(2a + c)\,bh}{6} = \frac{(2 \times 4 + 5) \times 3 \times 4.5}{6} = \frac{(8 + 5) \times 13.5}{6} = \frac{13 \times 13.5}{6}$$

$$= \frac{175.5}{6} = 29.25 \text{ cubic inches.}$$

Volumes of Solids



Cylinder

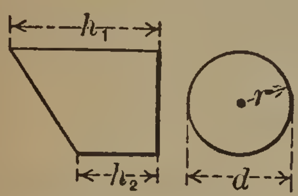
V = volume; S = area of cylindrical surface.

$V = 3.1416\, r^2h = 0.7854\, d^2h$

$S = 6.2832\, rh = 3.1416\, dh$

Total area A of cylindrical surface and end surfaces:

$A = 6.2832\, r\,(r + h) = 3.1416\, d\,(\frac{1}{2}\, d + h)$

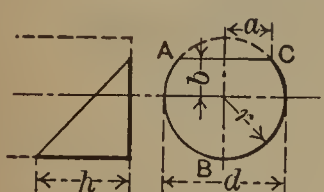


Portion of Cylinder

V = volume; S = area of cylindrical surface.

$V = 1.5708\, r^2\,(h_1 + h_2) = 0.3927\, d^2\,(h_1 + h_2)$

$S = 3.1416\, r\,(h_1 + h_2) = 1.5708\, d\,(h_1 + h_2)$



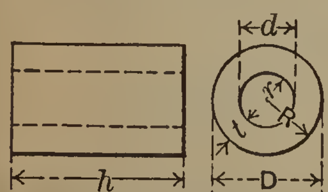
Portion of Cylinder

V = volume; S = area of cylindrical surface.

$$V = \left(\frac{2}{3}\, a^3 \pm b \times \text{area } ABC\right) \frac{h}{r \pm b}$$

$$S = (ad \pm b \times \text{length of arc } ABC)\, \frac{h}{r \pm b}$$

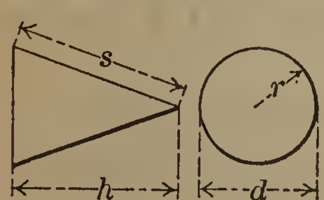
Use $+$ when base area is larger, and $-$ when base area is less than one-half the base circle.



Hollow Cylinder

V = volume.

$$\begin{aligned} V &= 3.1416\, h\,(R^2 - r^2) = 0.7854\, h\,(D^2 - d^2) \\ &= 3.1416\, ht\,(2\,R - t) = 3.1416\, ht\,(D - t) \\ &= 3.1416\, ht\,(2\,r + t) = 3.1416\, ht\,(d + t) \\ &= 3.1416\, ht\,(R + r) = 1.5708\, ht\,(D + d) \end{aligned}$$



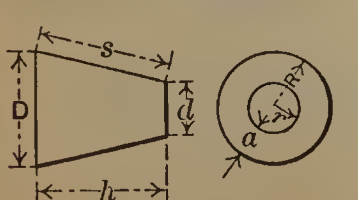
Cone

V = volume; A = area of conical surface.

$$V = \frac{3.1416\, r^2h}{3} = 1.0472\, r^2h = 0.2618\, d^2h$$

$$A = 3.1416\, r\sqrt{r^2 + h^2} = 3.1416\, rs = 1.5708\, ds$$

$$s = \sqrt{r^2 + h^2} = \sqrt{\frac{d^2}{4} + h^2}$$



Frustum of Cone

V = volume; A = area of conical surface.

$V = 1.0472\, h\,(R^2 + Rr + r^2) = 0.2618\, h\,(D^2 + Dd + d^2)$

$A = 3.1416\, s\,(R + r) = 1.5708\, s\,(D + d)$

$a = R - r \qquad s = \sqrt{a^2 + h^2} = \sqrt{(R - r)^2 + h^2}$

Examples of the Use of the Formulas

Cylinder. — The diameter of a cylinder is $2\frac{1}{2}$ inches. The length or height is 20 inches. Find the volume, and the area of the cylindrical surface S.

$$V = 0.7854\, d^2h = 0.7854 \times 2\tfrac{1}{2}^2 \times 20 = 0.7854 \times 6.25 \times 20 = 98.17 \text{ cubic inches.}$$
$$S = 3.1416\, dh = 3.1416 \times 2\tfrac{1}{2} \times 20 = 157.08 \text{ square inches.}$$

Portion of Cylinder. — A cylinder 5 inches in diameter, is cut off at an angle, as shown in the illustration. Dimension $h_1 = 6$, and $h_2 = 4$ inches. Find the volume and the area S of the cylindrical surface.

$$V = 0.3927\, d^2\,(h_1 + h_2) = 0.3927 \times 5^2 \times (6 + 4) = 0.3927 \times 25 \times 10$$
$$= 98.175 \text{ cubic inches.}$$
$$S = 1.5708\, d\,(h_1 + h_2) = 1.5708 \times 5 \times 10 = 78.54 \text{ square inches.}$$

Portion of Cylinder. — Find the volume of a cylinder so cut off that line AC passes through the center of the base circle — that is, the base area is a half-circle. The diameter of the cylinder = 5 inches, and height h = 2 inches.

In this case $a = 2.5$; $b = 0$; area $ABC = \frac{1}{2} \times 0.7854 \times 5^2 = 9.82$; $r = 2.5$.

$$V = \left(\frac{2}{3} \times 2.5^3 + 0 \times 9.82\right) \frac{2}{2.5 + 0} = \frac{2}{3} \times 15.625 \times 0.8 = 8.33 \text{ cubic inches.}$$

Hollow Cylinder. — A cylindrical shell, 28 inches high, is 36 inches in outside diameter, and 4 inches thick. Find its volume.

$$V = 3.1416\, ht\,(D - t) = 3.1416 \times 28 \times 4\,(36 - 4) = 3.1416 \times 28 \times 4 \times 32$$
$$= 11{,}259.5 \text{ cubic inches.}$$

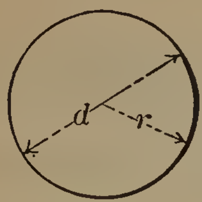
Cone. — Find the volume and area of conical surface of a cone, the base of which is a circle of 6 inches diameter, and the height of which is 4 inches.

$$V = 0.2618\, d^2h = 0.2618 \times 6^2 \times 4 = 0.2618 \times 36 \times 4 = 37.7 \text{ cubic inches.}$$
$$A = 3.1416\, r\sqrt{r^2 + h^2} = 3.1416 \times 3 \times \sqrt{3^2 + 4^2} = 9.4248 \times \sqrt{25}$$
$$= 47.124 \text{ square inches.}$$

Frustum of Cone. — Find the volume of a frustum of a cone of the following dimensions: D = 8 inches; d = 4 inches; h = 5 inches.

$$V = 0.2618 \times 5\,(8^2 + 8 \times 4 + 4^2) = 0.2618 \times 5\,(64 + 32 + 16)$$
$$= 0.2618 \times 5 \times 112 = 146.61 \text{ cubic inches.}$$

Volumes of Solids



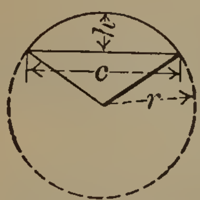
Sphere

V = volume; A = area of surface.

$$V = \frac{4\pi r^3}{3} = \frac{\pi d^3}{6} = 4.1888\, r^3 = 0.5236\, d^3$$

$$A = 4\pi r^2 = \pi d^2 = 12.5664\, r^2 = 3.1416\, d^2$$

$$r = \sqrt[3]{\frac{3\,V}{4\pi}} = 0.6204\sqrt[3]{V}$$



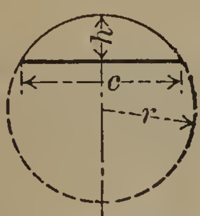
Spherical Sector

V = volume; A = total area of conical and spherical surface.

$$V = \frac{2\pi r^2 h}{3} = 2.0944\, r^2 h$$

$$A = 3.1416\, r\left(2\,h + \tfrac{1}{2}\,c\right)$$

$$c = 2\sqrt{h\,(2\,r - h)}$$



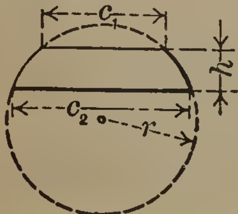
Spherical Segment

V = volume; A = area of spherical surface.

$$V = 3.1416\, h^2\left(r - \frac{h}{3}\right) = 3.1416\, h\left(\frac{c^2}{8} + \frac{h^2}{6}\right)$$

$$A = 2\pi r h = 6.2832\, rh = 3.1416\left(\frac{c^2}{4} + h^2\right)$$

$$c = 2\sqrt{h\,(2\,r - h)};\quad r = \frac{c^2 + 4\,h^2}{8\,h}$$



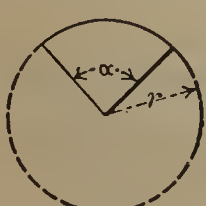
Spherical Zone

V = volume; A = area of spherical surface.

$$V = 0.5236\, h\left(\frac{3\,c_1^2}{4} + \frac{3\,c_2^2}{4} + h^2\right)$$

$$A = 2\pi r h = 6.2832\, rh$$

$$r = \sqrt{\frac{c_2^2}{4} + \left(\frac{c_2^2 - c_1^2 - 4\,h^2}{8\,h}\right)^2}$$



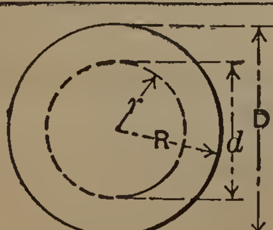
Spherical Wedge

V = volume; A = area of spherical surface;

α = center angle in degrees.

$$V = \frac{\alpha}{360} \times \frac{4\pi r^3}{3} = 0.0116\,\alpha r^3$$

$$A = \frac{\alpha}{360} \times 4\pi r^2 = 0.0349\,\alpha r^2$$



Hollow Sphere

V = volume.

$$V = \frac{4\pi}{3}\left(R^3 - r^3\right) = 4.1888\left(R^3 - r^3\right)$$

$$= \frac{\pi}{6}\left(D^3 - d^3\right) = 0.5236\left(D^3 - d^3\right)$$

Examples of the Use of the Formulas

Sphere. — Find the volume and surface of a sphere 6.5 inches in diameter.

$V = 0.5236\, d^3 = 0.5236 \times 6.5^3 = 0.5236 \times 6.5 \times 6.5 \times 6.5 = 143.79$ cubic inches.

$A = 3.1416\, d^2 = 3.1416 \times 6.5^2 = 3.1416 \times 6.5 \times 6.5 = 132.73$ square inches.

The volume of a sphere is 64 cubic inches. Find its radius.

$r = 0.6204 \sqrt[3]{64} = 0.6204 \times 4 = 2.4816$ inches.

Spherical Sector. — Find the volume of a sector of a sphere 6 inches in diameter, the height h of the sector being 1.5 inch. Also find length of chord c. — Here $r = 3$, and $h = 1.5$.

$V = 2.0944\, r^2h = 2.0944 \times 3^2 \times 1.5 = 2.0944 \times 9 \times 1.5 = 28.27$ cubic inches.

$c = 2\sqrt{h\,(2\,r - h)} = 2\sqrt{1.5\,(2 \times 3 - 1.5)} = 2\sqrt{6.75} = 2 \times 2.598$

$= 5.196$ square inches.

Spherical Segment. — A segment of a sphere has the following dimensions: $h = 2$ inches; $c = 5$ inches. Find the volume V and the radius of the sphere of which the segment is a part.

$$V = 3.1416 \times 2 \times \left(\frac{5^2}{8} + \frac{2^2}{6}\right) = 6.2832 \times \left(\frac{25}{8} + \frac{4}{6}\right) = 6.2832 \times 3.792$$

$= 23.825$ cubic inches.

$$r = \frac{5^2 + 4 \times 2^2}{8 \times 2} = \frac{25 + 16}{16} = \frac{41}{16} = 2\tfrac{9}{16} \text{ inches.}$$

Spherical Zone. — In a spherical zone, let $c_1 = 3$; $c_2 = 4$; and $h = 1.5$ inch. Find the volume.

$$V = 0.5236 \times 1.5 \times \left(\frac{3 \times 3^2}{4} + \frac{3 \times 4^2}{4} + 1.5^2\right) = 0.5236 \times 1.5 \times \left(\frac{27}{4} + \frac{48}{4} + 2.25\right)$$

$= 0.5236 \times 1.5 \times 21 = 16.493$ cubic inches.

Spherical Wedge. — Find the area of the spherical surface and the volume of a wedge of a sphere. The diameter of the sphere is 4 inches, and the center angle α is 45 degrees.

$V = 0.0116 \times 45 \times 2^3 = 0.0116 \times 45 \times 8 = 4.176$ cubic inches.

$A = 0.0349 \times 45 \times 2^2 = 0.0349 \times 45 \times 4 = 6.282$ square inches.

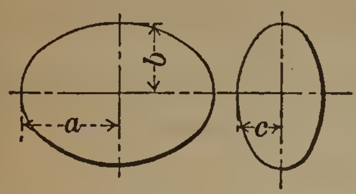
Hollow Sphere. — Find the volume of a hollow sphere, 8 inches in outside diameter, with a thickness of material of 1.5 inch.

Here $R = 4$; $r = 4 - 1.5 = 2.5$.

$V = 4.1888\,(4^3 - 2.5^3) = 4.1888\,(64 - 15.625) = 4.1888 \times 48.375$

$= 202.63$ cubic inches.

Volumes of Solids



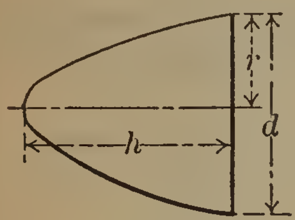
Ellipsoid

V = volume; A = area of surface.

$$V = \frac{4\pi}{3} abc = 4.1888\, abc$$

In an ellipsoid of revolution, or spheroid, where $b = c$:

$$V = 4.1888\, ab^2, \quad \text{and} \quad A = \frac{4\pi}{\sqrt{2}} b \sqrt{a^2 + b^2}$$

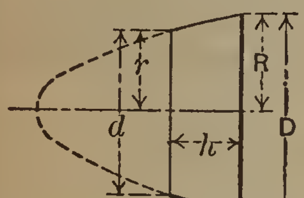


Paraboloid

V = volume; $V = \frac{1}{2}\pi r^2 h = 0.3927\, d^2 h$

A = area; $A = \frac{2\pi}{3p}\left[\sqrt{\left(\frac{d^2}{4} + p^2\right)^3} - p^3\right]$ in which

$$p = \frac{d^2}{8h}$$

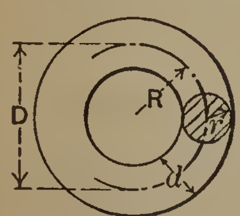


Paraboloidal Segment

V = volume.

$$V = \frac{\pi}{2} h\,(R^2 + r^2) = 1.5708\, h\,(R^2 + r^2)$$

$$= \frac{\pi}{8} h\,(D^2 + d^2) = 0.3927\, h\,(D^2 + d^2)$$



Torus

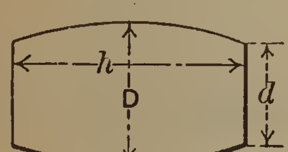
V = volume; A = area of surface.

$$V = 2\pi^2 Rr^2 = 19.739\, Rr^2$$

$$= \frac{\pi^2}{4} Dd^2 = 2.4674\, Dd^2$$

$$A = 4\pi^2 Rr = 39.478\, Rr$$

$$= \pi^2 Dd = 9.8696\, Dd$$



Barrel

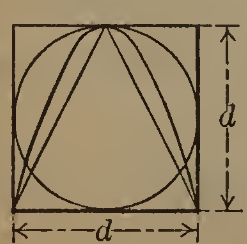
V = approximate volume.

If the sides are bent to the arc of a circle:

$$V = \tfrac{1}{12}\pi h\,(2D^2 + d^2) = 0.262\, h\,(2D^2 + d^2)$$

If the sides are bent to the arc of a parabola:

$$V = 0.209\, h\,(2D^2 + Dd + \tfrac{3}{4} d^2)$$



If d = base diameter and height of a cone, a paraboloid and a cylinder, and the diameter of a sphere, then the volumes of these bodies are to each other as below:

Cone: paraboloid: sphere: cylinder $= \frac{1}{3} : \frac{1}{2} : \frac{2}{3} : 1$

Examples of the Use of the Formulas

Ellipsoid or Spheroid. — Find the volume and area of surface of a spheroid in which $a = 5$, and $b = c = 1.5$ inch.

$$V = 4.1888 \times 5 \times 1.5^2 = 4.1888 \times 5 \times 2.25 = 47.124 \text{ cubic inches.}$$

$$A = \frac{4 \times 3.1416}{\sqrt{2}} \times 1.5 \times \sqrt{5^2 + 1.5^2} = \frac{4 \times 3.1416}{1.414} \times 1.5 \times 5.22 = 69.57 \text{ sq. inches.}$$

Paraboloid. — Find the volume of a paraboloid in which $h = 12$ and $d = 5$ inches.

$$V = 0.3927\, d^2h = 0.3927 \times 5^2 \times 12 = 0.3927 \times 25 \times 12$$
$$= 0.3927 \times 300 = 117.81 \text{ cubic inches.}$$

Segment of Paraboloid. — Find the volume of a segment of a paraboloid in which $D = 5$ inches, $d = 3$ inches, and $h = 6$ inches.

$$V = 0.3927\, h\,(D^2 + d^2) = 0.3927 \times 6 \times (5^2 + 3^2) = 0.3927 \times 6 \times (25 + 9)$$
$$= 0.3927 \times 6 \times 34 = 80.11 \text{ cubic inches.}$$

Torus. — Find the volume and area of surface of a torus in which $d = 1.5$ and $D = 5$ inches.

$$V = 2.4674 \times 5 \times 1.5^2 = 2.4674 \times 5 \times 2.25 = 27.76 \text{ cubic inches.}$$

$$A = 9.8696 \times 5 \times 1.5 = 74.022 \text{ square inches}$$

Barrel. — Find the approximate contents of a barrel, the inside dimensions of which are $D = 24$ inches; $d = 20$ inches; $h = 48$ inches.

$$V = 0.262\, h\,(2\,D^2 + d^2) = 0.262 \times 48 \times (2 \times 24^2 + 20^2) = 0.262 \times 48$$
$$\times (1152 + 400) = 0.262 \times 48 \times 1552 = 19{,}518 \text{ cubic inches.}$$

Assume, as an example, that the diameter of the base of a cone, paraboloid and cylinder is 2 inches, that the height is 2 inches, and that the diameter of a sphere is 2 inches. Then the volumes, written in formula-form, are as below:

Cone	Paraboloid	Sphere	Cylinder

$$\frac{3.1416 \times 2^2 \times 2}{12} : \frac{3.1416 \times 2^2 \times 2}{8} : \frac{3.1416 \times 2^3}{6} : \frac{3.1416 \times 2^2 \times 2}{4} = \frac{1}{3} : \frac{1}{2} : \frac{2}{3} : 1$$

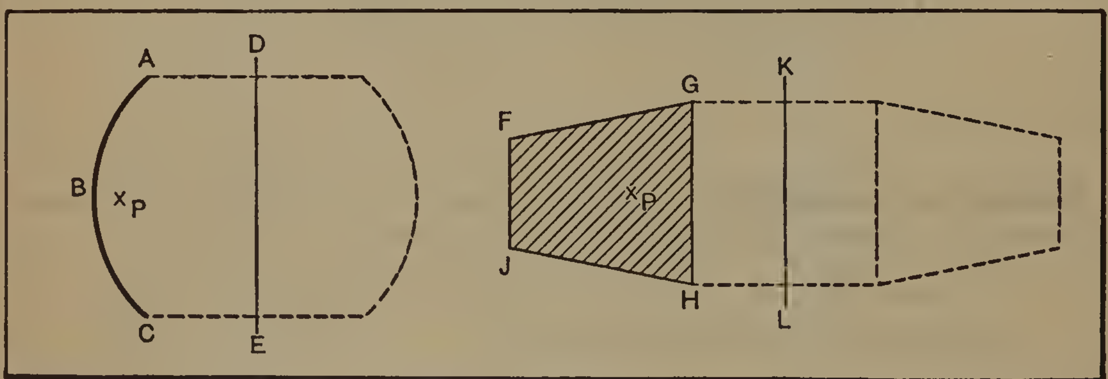
The Prismoidal Formula. — The prismoidal formula is a general formula by which the volume of any prism, pyramid or frustum of a pyramid may be found.

A_1 = area at one end of the body;
A_2 = area at the other end;
A_m = area of middle section between the two end surfaces;
h = height of body.

Then, volume V of the body is

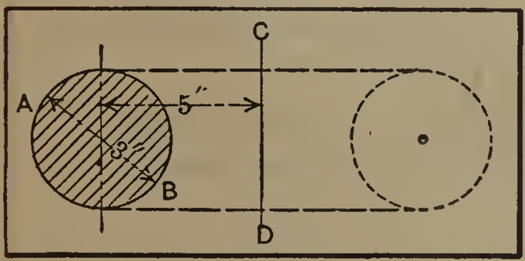
$$V = \frac{h}{6}(A_1 + 4A_m + A_2)$$

Pappus or Guldinus Rules. — By means of these rules the area of any surface of revolution and the volume of any solid of revolution may be found. The area of the surface swept out by the revolution of a line ABC (see illustration) about the axis DE equals the length of the line multiplied by the length of the path



of its center of gravity, P. If the line is of such a shape that it is difficult to determine its center of gravity, then the line may be divided into a number of short sections, each of which may be considered as a straight line, and the areas swept out by these different sections, as computed by the rule given, may be added to find the total area. The line must lie wholly on one side of the axis of revolution and must be in the same plane.

The volume of a solid body formed by the revolution of a surface $FGHJ$ about axis KL equals the area of the surface multiplied by the length of the path of its center of gravity. The surface must lie wholly on one side of the axis of revolution and in the same plane.



Example: — By means of these rules the area and volume of a cylindrical ring or torus may be found. The torus is formed by a circle AB being rotated about axis CD. The center of gravity of the circle is at its center. Hence, with the dimensions given in the illustration, the length of the path of the center of gravity of the circle is $3.1416 \times 10 = 31.416$ inches. This multiplied by the length of the circumference of the circle, which is $3.1416 \times 3 = 9.4248$ inches, equals:

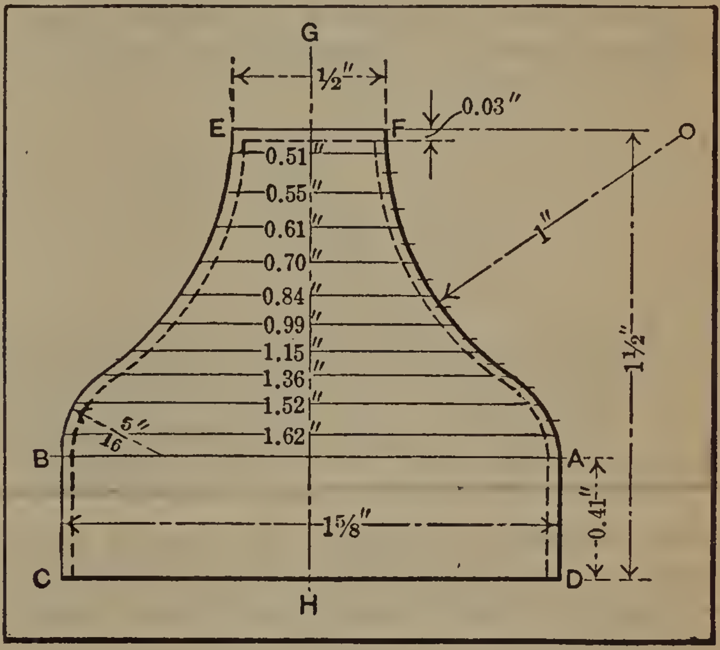
$$31.416 \times 9.4248 = 296.089 \text{ square inches}$$

which is the area of the torus.

The volume equals the area of the circle, which is $0.7854 \times 9 = 7.0686$ square inches, multiplied by the path of the center of gravity, which is 31.416, as before; hence,

$$\text{volume} = 7.0686 \times 31.416 = 222.067 \text{ cubic inches.}$$

Example of Approximate Method for Finding the Area of a Surface of Revolution. — The accompanying illustration is shown in order to give an example of the approximate method based on Guldinus' rule, that can be used for finding the area of a symmetrical body. In the illustration, the dimensions in common fractions are the known dimensions; those in decimals are found by actual measurements on a figure drawn to scale. The method for finding the area is as follows: First separate such areas as are cylindrical, conical or spherical, as these can be found by exact formulas. In the illustration *ABCD* is a cylinder, the area of the surface of which can be easily found. The top area *EF* is simply a circular area, and can thus be computed separately. The remainder of the surface generated by rotating line *AF* about the axis *GH* is found by the approximate method explained in the previous section. From point *A*, set off equal distances on line *AF*. In the present case each division indicated is ⅛ inch long. From the central or middle point of each of these parts draw a line at right angles to the axis of rotation *GH*, measure the length of these lines or diameters (the length of each is given in decimals), add all these lengths together and multiply the sum by the length of one division set off on line *AF* (in this case, ⅛ inch), and multiply this product by π. This gives the approximate area of the surface of revolution.



In setting off divisions ⅛ inch long along line *AF*, the last division does not reach exactly to point *F*, but only to a point 0.03 inch below it. The part 0.03 inch high at the top of the cup, can be considered as a cylinder of ½ inch diameter and 0.03 inch height, the area of the cylindrical surface of which is easily computed. By adding the various surfaces together the total surface of the cup is found as below:

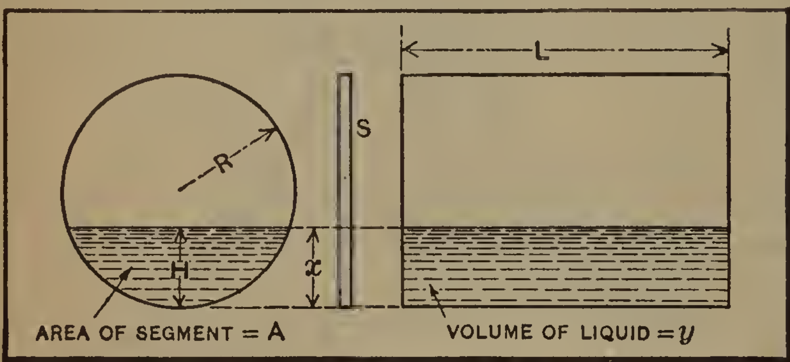
Cylinder, 1⅝ inch diameter, 0.41 inch high........	2.093 square inches
Circle, ½ inch diameter..........................	0.196 square inches
Cylinder, ½ inch diameter, 0.03 inch high.........	0.047 square inches
Irregular surface................................	3.868 square inches
Total..	6.204 square inches

Plane Surfaces of Irregular Outline. — The areas of plane surfaces of irregular outline can best be found by dividing the surfaces into a number of geometrical figures, the areas of which can be found by the general rules and formulas. The most convenient method is, as a rule, to divide the area into a number of narrow strips which may be regarded as rectangles, the base of the rectangle being the width of the strip, and a line through the center of the strip its mean height. Surfaces of irregular outline, having straight boundary lines, are most conveniently divided into a number of triangles, the areas of which can be readily found and added together.

Areas Enclosed by Cycloidal Curves. — The area between a cycloid and the straight line upon which the generating circle rolls, equals three times the area of the generating circle (see diagram, page 154). The areas between epicycloidal and hypocycloidal curves and the "fixed circle" upon which the generating circle is rolled, may be determined by the following formulas, in which a = radius of the fixed circle upon which the generating circle rolls; b = radius of the generating circle; A = the area for the epicycloidal curve; and A_1 = the area for the hypocycloidal curve.

$$A = \frac{3.1416\, b^2\,(3\,a + 2\,b)}{a}; \qquad A_1 = \frac{3.1416\, b^2\,(3\,a - 2\,b)}{a}$$

Finding the Contents of Cylindrical Tanks at Different Levels. — The following method for determining the contents of a cylindrical tank at any given level may be employed for locating the graduations on gage sticks such as are used for measuring approximately the contents, by inserting the gage vertically in the center of the tank with the lower end against the bottom and noting the relation between the level of the liquid and the graduation marks which indicate the number of gallons. The table "Segments of Circles" (see pages 72 and 73) is used to simplify the calculations. Column H of this table gives the values for the heights of segments with different center angles and for unit radius; or, in other words, the ratio: $\frac{\text{height of segment}}{\text{radius}}$. Another column gives the area of the segment in a circle of unit radius. The area of a similar segment of larger radius is this area multiplied by the given radius squared. Let



L = length of tank, in inches (see accompanying illustration);

R = radius in inches;

H = height of segment for unit radius = $\frac{\text{height}}{R}$;

y = capacity, in gallons, for which graduation is to be found on scale S;

x = distance from graduation mark to nearest end of scale;

$U = \frac{L}{231}$ gallons in one-inch square section, the length of which equals the length of the tank;

a = corresponding area in table giving areas for segments of unit radius;

A = area of segment of given radius.

As $H = \frac{\text{height}}{R} = \frac{x}{R}$, $x = HR$; also, by the rule at the head of the table, the area of a segment of given radius, or A, equals aR^2. The number of gallons represented by a graduation on the scale, or y, equals $AU = aR^2U$, and $a = \frac{y}{R^2U}$. Therefore, R^2U is a constant for any given tank. The method of procedure will be illustrated by a practical example.

Example: — A tank is 20 feet long and 6 feet in diameter, and the graduation mark representing 1000 gallons is to be located on a scale. Find the distance from the graduation mark to the nearest end of the scale.

As the radius of the tank is 36 inches and the length 240 inches, the total capacity, in this case, equals:

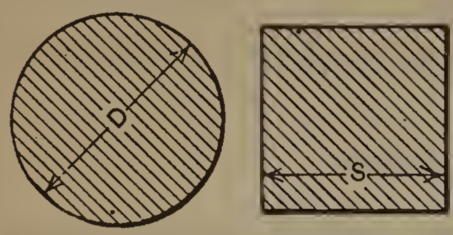
$$\frac{3.1416 \times 36^2 \times 240}{231} = 4230 \text{ gallons.}$$

As the graduation mark is to represent 1000 gallons, which is less than one-half the total capacity, this graduation will be located with reference to the lower end of the scale. The constant R^2U, for this tank, is $36^2 \times \frac{240}{231} = 1346$. As $a = \frac{y}{R^2U}$, the corresponding area of a segment of unit radius is $1000 \div 1346 = 0.743$. The table shows that this area is greater than the corresponding area of a segment of 129 degrees, and less than the area of a 130-degree segment. By interpolation, the value of H is found to be about 0.573. As $x = HR$, the graduation mark on the scale for 1000 gallons is $0.573 \times 36 = 20.62$ inches from the lower end.

In the preceding example, if a graduation mark were required to represent, say, 3000 gallons, this mark would be located from the top of the scale, because 3000 is more than one-half the total capacity of the tank. In this case, the value of y equals the difference between the total capacity and the number of gallons which the graduation is to represent. Thus, in this case, $y = 4230 - 3000 = 1230$, and $a = 1230 \div 1346 = 0.914$. By interpolation, the corresponding value of H is found to be 0.665. Therefore, $x = 0.665 \times 36 = 23.94$ inches for the 3000-gallon graduation mark.

Determining Areas with a Planimeter. — The area of a plane figure may be determined readily by means of a planimeter even though the figure is very irregular in outline. This type of instrument is extensively used for obtaining the areas of steam engine indicator cards. (After finding the area, in square inches, this area is divided by the length of the card, in inches, to obtain the average height; the quotient is then multiplied by the scale of the indicator spring and the result equals the mean effective pressure.) When using the planimeter the "tracing point" is moved along the outline of the area or surface to be measured. The "Amsler polar planimeter," which is a common form, has two arms; the end of one arm has a needle point by means of which it is attached to the paper on which the outline is drawn. The arm that is fixed to the paper has a standard length, while the tracing arm can be adjusted so that the results may be read in different units. The instrument is so connected with a graduated wheel, the periphery of which rests upon the paper, that the area can be read off on the wheel and its vernier. The planimeter may also have a disk for counting the number of revolutions made by the wheel. The tracing point must be moved carefully around the outline until the starting point is again reached. The area is determined by the difference of the reading on the disk and the graduated wheel at the beginning of the measuring movement and at the end. If the planimeter is too small to measure a given area, the area can be divided and the sections measured separately. The results obtained by the polar planimeter are correct within an error of about one per cent. The rolling planimeter, which is a more expensive type, gives results that are correct within about 0.1 per cent. The whole instrument rolls forward and backward in a straight line while the tracing point follows the outline of the surface to be measured. This type is adapted for measuring figures of indefinite length and limited breadth. Some planimeters give results in various denominations of value, such as square inches, square feet, and square decimeters, and also the average height of an indicator diagram at one measurement or by a direct reading, after tracing the outline.

Diameters of Circles and Sides of Squares of Equal Area



The table below will be found useful for determining the diameter of a circle of an area equal to that of a square, the side of which is known, or for determining the side of a square which has an area equal to that of a circle, the area or diameter of which is known. For example, if the diameter of a circle is 17½ inches, it is found from the table that the side of a square of the same area is 15.51 inches.

Diam. of Circle, *D*	Side of Square, *S*	Area of Circle or Square	Diam. of Circle, *D*	Side of Square, *S*	Area of Circle or Square	Diam. of Circle, *D*	Side of Square *S*	Area of Circle or Square
½	0.44	0.196	20½	18.17	330.06	40½	35.89	1288.25

SOLUTION OF TRIANGLES

Any figure bounded by three straight lines is called a triangle. Any one of the three lines may be called the base, and the line drawn from the angle opposite the base at right angles to it is called the height or altitude of the triangle.

If all the three sides of a triangle are of equal length, the triangle is called *equilateral*. Each one of the three angles in an equilateral triangle equals 60 degrees. If two sides are of equal length, the triangle is an *isosceles* triangle. If one angle is a right or 90-degree angle, the triangle is a *right* or *right-angled* triangle. The side opposite the right angle is called the *hypotenuse*.

If all the angles are less than 90 degrees, the triangle is called an *acute* or *acute-angled* triangle. If one of the angles is larger than 90 degrees, the triangle is called an *obtuse-angled* triangle. Both acute and obtuse-angled triangles are known under the common name of *oblique-angled* triangles. The sum of the three angles in every triangle is 180 degrees.

The sides and angles of any triangle which are not known can be found when: 1. All the three sides; 2. Two sides and one angle; or, 3. One side and two angles, are given. In other words, if a triangle is considered as consisting of six parts, three angles and three sides, the unknown parts can be determined when any three parts are given, provided at least one of the given parts is a side.

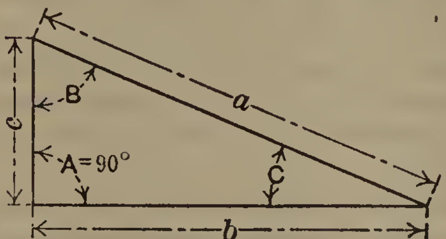
Functions of Angles. — The functions of angles used in solving triangles are sine, cosine, tangent, cotangent, secant, and cosecant. These expressions are usually abbreviated as follows:

sin = sine,	cot = cotangent,
cos = cosine,	sec = secant,
tan = tangent,	cosec = cosecant.

If in a right-angled triangle (see the illustration in the table below), the lengths of the three sides are represented by a, b and c, and the angles opposite each of these sides by A, B and C, then the side a opposite the right angle is the hypotenuse;

Trigonometrical Functions of Angles

The *sine* of an angle equals the opposite side divided by the hypotenuse. Hence, $\sin B = b \div a$, and $\sin C = c \div a$.



The *cosine* of an angle equals the adjacent side divided by the hypotenuse. Hence, $\cos B = c \div a$, and $\cos C = b \div a$.

The *tangent* of an angle equals the opposite side divided by the adjacent side. Hence, $\tan B = b \div c$, and $\tan C = c \div b$.

The *cotangent* of an angle equals the adjacent side divided by the opposite side. Hence, $\cot B = c \div b$, and $\cot C = b \div c$.

The *secant* of an angle equals the hypotenuse divided by the adjacent side. Hence, $\sec B = a \div c$, and $\sec C = a \div b$.

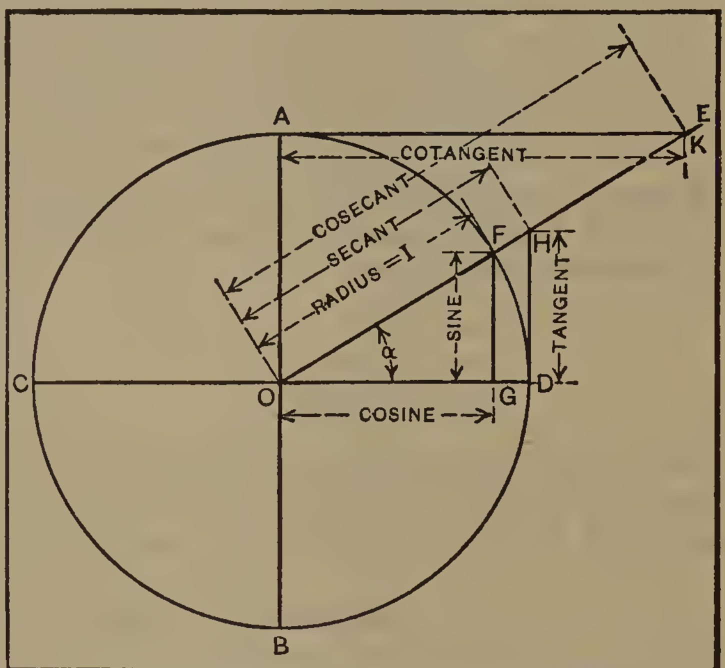
The *cosecant* of an angle equals the hypotenuse divided by the opposite side. Hence, $\operatorname{cosec} B = a \div b$, and $\operatorname{cosec} C = a \div c$.

It should be noted that the functions of the angles can be found in this manner only when the triangle is right-angled.

side b is called the *side adjacent* to angle C and is also the *side opposite* to angle B; side c is the side adjacent to angle B and the side opposite to angle C. The meanings of the various functions of angles can be explained by the aid of a right-angled triangle.

The following relation exists between the angular functions of the two acute angles in a right-angled triangle: The sine of angle B equals the cosine of angle C; the tangent of angle B equals the cotangent of angle C, and *vice versa*. The sum of the two acute angles in a right-angled triangle always equals 90 degrees; hence, when one angle is known, the other can easily be found. When any two angles together make 90 degrees, one is called the *complement* of the other, and in that case the sine of the one equals the cosine of the other, and the tangent of the one equals the cotangent of the other.

Graphic Illustrations of the Functions of Angles. — Draw a circle with a radius 1, as shown in the accompanying illustration. Draw two lines AB and CD at right angles to each other through the center of the circle; then draw a line OE from the center O forming an angle α with line OD. The sine for this angle is represented by line FG, drawn from point F where OE intersects the periphery of the circle, at right angles to CD. The cosine of angle α is represented by line OG. The tangent of the angle is represented by line DH drawn from point D at right angles to CD. The cotangent is represented by line AK drawn from point A at right angles to AB. The secant is represented by OH, and the cosecant by OK.



In graphically illustrating the functions of angles, it is assumed that all distances measured in the horizontal direction to the right of line AB are positive. Those measured horizontally to the left of AB are negative. All distances measured vertically, are positive above line CD and negative below it. It can then be readily seen that the sine is positive for all angles less than 180 degrees. For angles larger than 180 degrees, the sine would be measured below CD, and is negative. The cosine is positive up to 90 degrees, but for angles larger than 90 but less than 270 degrees, the cosine is measured to the left of line AB and is negative.

On the next page a table "Changes in Value and Sign of Trigonometrical Functions" is given. This table is arranged to show directly whether the function of any given angle is positive or negative. It also gives the limits between which the numerical values of the function vary. For example, it will be seen from the table that the cosine of an angle between 90 and 180 degrees is negative, and that its value will be somewhere between 0 and − 1. In the same way, the cotangent of an angle between 180 and 270 degrees is positive and has a value between infinity and 0; in other words, the cotangent for 180 degrees is infinitely large and then the cotangent gradually decreases for increasing angles, so that the cotangent for 270 degrees equals 0.

Tables of Trigonometric Functions. — The numerical values for the natural or trigonometric functions for all degrees and minutes are given in the tables in the following. When the sine, cosine, tangent, etc., of an angle between 0 and 45 degrees is to be found, the given number of degrees is found at the top of the table and the given number of minutes in the extreme left-hand column. Then read off the figures opposite the given number of minutes, in the columns headed sine, cosine, tangent, etc.

When the sine, cosine, etc., of an angle between 45 and 90 degrees is to be found, the number of degrees is found at the bottom of the table and the number of minutes in the extreme right-hand column. Then read off the required function opposite the number of minutes in the column marked with the required function at the *bottom*. The functions for angles greater than 90 degrees are also found from these

Changes in Value and Sign of Trigonometrical Functions

Function	Between 0° and 90°	Between 90° and 180°	Between 180° and 270°	Between 270° and 360°
Sine	Positive From 0 to 1	Positive From 1 to 0	Negative From 0 to − 1	Negative From − 1 to 0
Cosine	Positive From 1 to 0	Negative From 0 to − 1	Negative From − 1 to 0	Positive From 0 to 1
Tangent	Positive From 0 to ∞	Negative From ∞ to 0	Positive From 0 to ∞	Negative From ∞ to 0
Cotangent	Positive From ∞ to 0	Negative From 0 to ∞	Positive From ∞ to 0	Negative From 0 to ∞
Secant	Positive From 1 to ∞	Negative From ∞ to − 1	Negative From − 1 to ∞	Positive From ∞ to 1
Cosecant	Positive From ∞ to 1	Positive From 1 to ∞	Negative From ∞ to − 1	Negative From − 1 to ∞

tables, as indicated by the numbers in the upper right-hand and lower left-hand corners of the tables. For angles between 90 and 135 degrees, the minutes are read in the extreme left-hand column but the functions are read at the bottom of the table. For angles between 135 and 180 degrees, the minutes are read in the extreme right-hand column and the functions at the head of the table.

The sine is positive for all angles up to 180 degrees. The cosine, tangent and cotangent for angles between 90 and 180 degrees, while they have the same numerical values as for angles from 0 to 90 degrees, are negative. These should be preceded by a minus sign; thus tan 123 degrees 20 minutes = − 1.5204.

Formulas for the solution of right-angled and oblique-angled triangles, arranged in tabular form, are given on the following pages.

Measuring Angles in Radians. — While in practical work angles are always measured in degrees and minutes, the system for measuring angles in what is termed *circular measure* is often employed in theoretical investigations and in formulas relating to revolving bodies. In this system the unit of measurement is the *radian*, that is, the angle at the center of a circle which embraces an arc equal in length to the length of the radius. The value of the radian in degrees equals $180 \div \pi = 57.2958$ degrees. In this measurement, then, π denotes an angle of 180 degrees, and $\pi \div 2$, an angle of 90 degrees.

It is especially convenient to measure angles in radians when dealing with angular velocity. If ω = angular velocity per second of the revolving body, in radians; v = velocity of a point on the periphery of the body, in feet per second; and r = the radius, in feet, then:

$$\omega = \frac{v}{r}$$

For example, assume that the velocity of a point on the periphery is 20 feet per second and the radius, 2 feet. Then the angular velocity is found as below:

$$\omega = \frac{20}{2} = 10 \text{ radians.}$$

The simple manner in which the relation between the angular velocity, the linear velocity, and the radius or diameter of the revolving body can be expressed, is the reason for using the radian as a unit of angular measurement.

The Law of Sines. — In a triangle, any side is to any other side as the sine of the angle opposite the first side is to the sine of the angle opposite the other side; or, if a and b be the sides, and A and B the angles opposite them:

$$\frac{a}{b} = \frac{\sin A}{\sin B}$$

The Law of Cosines. — In a triangle, the square of any side is equal to the sum of the squares of the other two sides minus twice their product times the cosine of the included angle; or if a, b and c be the sides and the angle opposite side a be denoted A, then:

$$a^2 = b^2 + c^2 - 2\,bc \cos A$$

These two laws, together with the proposition that the sum of the three angles equals 180 degrees, are the basis of all formulas relating to the solution of triangles.

Use of Tables of Squares in Solving Right-angled Triangles. — The tables of squares at the beginning of the book may be used to advantage in solving right-angled triangles. Assume that the sides including the right angle are known, and that they are $1\frac{5}{8}$ and $1\frac{7}{8}$ inch, respectively. Find the side opposite the right angle.

$$\text{Side to be found} = \sqrt{1.625^2 + 1.875^2}$$

From tables of squares:

$$\begin{aligned} 1.625^2 &= 2.640625 \\ 1.875^2 &= \underline{3.515625} \\ & 6.156250 \end{aligned}$$

By looking up the figures 615 in the number column in the tables, and finding the square root, we get the figures 24.799. The square root of 616 is 24.819. Hence, by estimating, the square root of $615.625 = 24.812$. As we want the square root of 6.15625, move the decimal point in the root one step to the left; then $\sqrt{6.15625} = 2.4812$. This is the length of the side opposite the right angle.

Important Trigonometric Formulas

$$\sin^2 A + \cos^2 A = 1 \qquad \tan A = \frac{\sin A}{\cos A} = \frac{1}{\cot A}$$

$$\cot A = \frac{\cos A}{\sin A} = \frac{1}{\tan A} \qquad \sec A = \frac{1}{\cos A} \qquad \operatorname{cosec} A = \frac{1}{\sin A}$$

$$\sin A = \sqrt{1 - \cos^2 A} = \frac{\tan A}{\sqrt{1 + \tan^2 A}} = \frac{1}{\sqrt{1 + \cot^2 A}}$$

$$\cos A = \sqrt{1 - \sin^2 A} = \frac{1}{\sqrt{1 + \tan^2 A}} = \frac{\cot A}{\sqrt{1 + \cot^2 A}}$$

$$\sin (A + B) = \sin A \cos B + \cos A \sin B$$

$$\sin (A - B) = \sin A \cos B - \cos A \sin B$$

$$\cos (A + B) = \cos A \cos B - \sin A \sin B$$

$$\cos (A - B) = \cos A \cos B + \sin A \sin B$$

$$\tan (A + B) = \frac{\tan A + \tan B}{1 - \tan A \tan B} \qquad \tan (A - B) = \frac{\tan A - \tan B}{1 + \tan A \tan B}$$

$$\cot (A + B) = \frac{\cot A \cot B - 1}{\cot B + \cot A} \qquad \cot (A - B) = \frac{\cot A \cot B + 1}{\cot B - \cot A}$$

$$\tan A + \tan B = \frac{\sin (A + B)}{\cos A \cos B} \qquad \tan A - \tan B = \frac{\sin (A - B)}{\cos A \cos B}$$

$$\cot A + \cot B = \frac{\sin (B + A)}{\sin A \sin B} \qquad \cot A - \cot B = \frac{\sin (B - A)}{\sin A \sin B}$$

$$\sin^2 A - \sin^2 B = \cos^2 B - \cos^2 A = \sin (A + B) \sin (A - B)$$

$$\cos^2 A - \sin^2 B = \cos^2 B - \sin^2 A = \cos (A + B) \cos (A - B).$$

$$\sin A \sin B = \tfrac{1}{2} \cos (A - B) - \tfrac{1}{2} \cos (A + B).$$

$$\cos A \cos B = \tfrac{1}{2} \cos (A - B) + \tfrac{1}{2} \cos (A + B)$$

$$\sin A \cos B = \tfrac{1}{2} \sin (A + B) + \tfrac{1}{2} \sin (A - B)$$

$$\tan A \tan B = \frac{\tan A + \tan B}{\cot A + \cot B} \qquad \cot A \cot B = \frac{\cot A + \cot B}{\tan A + \tan B}$$

$$\sin A = 2 \sin \tfrac{1}{2} A \cos \tfrac{1}{2} A \qquad \sin 2A = 2 \sin A \cos A$$

$$\cos 2A = \cos^2 A - \sin^2 A = 1 - 2 \sin^2 A = 2 \cos^2 A - 1$$

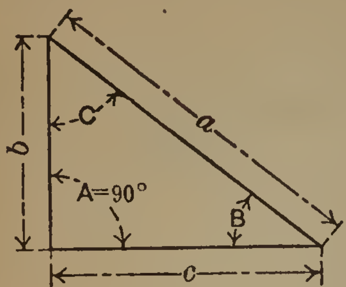
$$\tan 2A = \frac{2 \tan A}{1 - \tan^2 A} = \frac{2}{\cot A - \tan A}$$

$$\cot 2A = \frac{\cot^2 A - 1}{2 \cot A} = \frac{\cot A - \tan A}{2}$$

$$\sin A = \frac{2 \tan \tfrac{1}{2} A}{1 + \tan^2 \tfrac{1}{2} A} \qquad \cos A = \frac{1 - \tan^2 \tfrac{1}{2} A}{1 + \tan^2 \tfrac{1}{2} A}$$

$$2 \sin^2 A = 1 - \cos 2A \qquad 2 \cos^2 A = 1 + \cos 2A$$

Solution of Right-angled Triangles

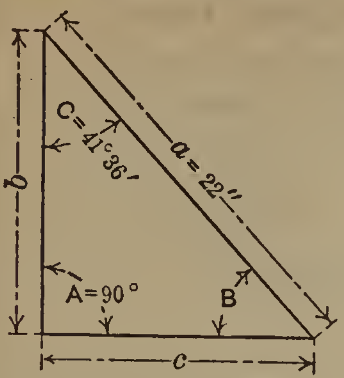


As shown in the illustration, the sides of the right-angled triangle are designated a, b and c. The angles opposite each of these sides are designated A, B and C, respectively.

Angle A, opposite the hypotenuse a is the right angle, and is therefore always one of the known quantities.

Sides and Angles Known	Formulas for Sides and Angles to be Found		
Sides a and b..........	$c = \sqrt{a^2 - b^2}$	$\sin B = \frac{b}{a}$	$C = 90° - B$
Sides a and c..........	$b = \sqrt{a^2 - c^2}$	$\sin C = \frac{c}{a}$	$B = 90° - C$
Sides b and c..........	$a = \sqrt{b^2 + c^2}$	$\tan B = \frac{b}{c}$	$C = 90° - B$
Side a; angle B........	$b = a \times \sin B$	$c = a \times \cos B$	$C = 90° - B$
Side a; angle C........	$b = a \times \cos C$	$c = a \times \sin C$	$B = 90° - C$
Side b; angle B........	$a = \frac{b}{\sin B}$	$c = b \times \cot B$	$C = 90° - B$
Side b; angle C........	$a = \frac{b}{\cos C}$	$c = b \times \tan C$	$B = 90° - C$
Side c; angle B........	$a = \frac{c}{\cos B}$	$b = c \times \tan B$	$C = 90° - B$
Side c; angle C........	$a = \frac{c}{\sin C}$	$b = c \times \cot C$	$B = 90° - C$

Examples of the Solution of Right-angled Triangles



Sides and angles known:

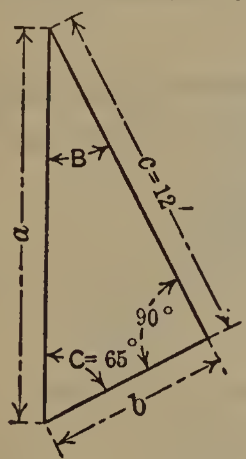
$$a = 22 \text{ inches}; \quad C = 41^\circ\ 36'.$$

Then, by the formulas given on the preceding page:

$$b = a \times \cos C = 22 \times \cos 41^\circ\ 36' = 22 \times 0.74780$$
$$= 16.4516 \text{ inches.}$$

$$c = a \times \sin C = 22 \times \sin 41^\circ\ 36' - 22 \times 0.66393$$
$$= 14.6065 \text{ inches.}$$

$$B = 90^\circ - 41^\circ\ 36' = 48^\circ\ 24'.$$



Sides and angles known:

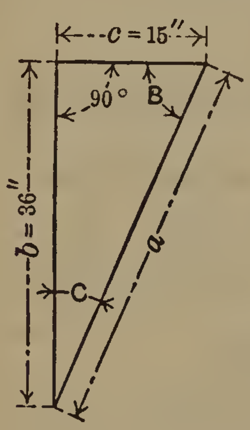
$$c = 12 \text{ feet}; \quad C = 65^\circ.$$

Then, by the formulas given on the preceding page:

$$a = \frac{c}{\sin C} = \frac{12}{\sin 65^\circ} = \frac{12}{0.90631} = 13.2405 \text{ feet.}$$

$$b = c \times \cot C = 12 \times \cot 65^\circ = 12 \times 0.46631$$
$$= 5.5957 \text{ feet.}$$

$$B = 90^\circ - 65^\circ = 25^\circ.$$



Sides known:

$$b = 36 \text{ inches}; \quad c = 15 \text{ inches.}$$

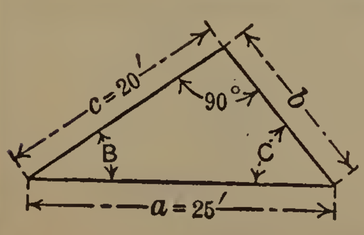
Then, by the formulas given on the preceding page:

$$a = \sqrt{b^2 + c^2} = \sqrt{36^2 + 15^2} = \sqrt{1296 + 225}$$
$$= \sqrt{1521} = 39 \text{ inches.}$$

$$\tan B = \frac{b}{c} = \frac{36}{15} = 2.4$$

Hence, $B = 67^\circ\ 23'$.

$$C = 90^\circ - 67^\circ\ 23' = 22^\circ\ 37'.$$



Sides known:

$$a = 25 \text{ feet}; \quad c = 20 \text{ feet.}$$

From the formulas on the preceding page:

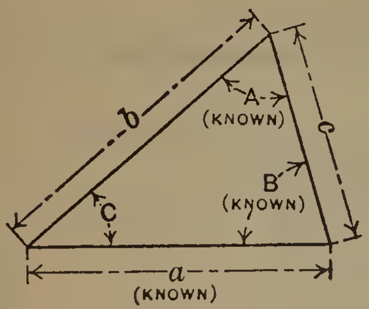
$$b = \sqrt{a^2 - c^2} = \sqrt{25^2 - 20^2} = \sqrt{625 - 400}$$
$$= \sqrt{225} = 15 \text{ feet.}$$

$$\sin C = \frac{c}{a} = \frac{20}{25} = 0.8$$

Hence, $C = 53^\circ\ 8'$.

$$B = 90^\circ - 53^\circ\ 8' = 36^\circ\ 52'.$$

Solution of Oblique-angled Triangles



One side and two angles known.

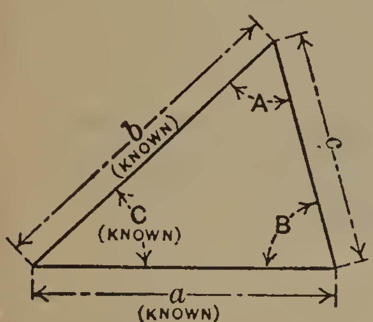
Call the known side a, the angle opposite it A, and the other known angle B. Then:

$$C = 180^\circ - (A + B)$$

$$b = \frac{a \times \sin B}{\sin A} \qquad c = \frac{a \times \sin C}{\sin A}$$

$$\text{Area} = \frac{a \times b \times \sin C}{2}$$

If angles B and C are given, but not A, then $A = 180^\circ - (B + C)$, the other formulas being the same.



Two sides and the angle between them known.

Call the known sides a and b, and the known angle between them C. Then:

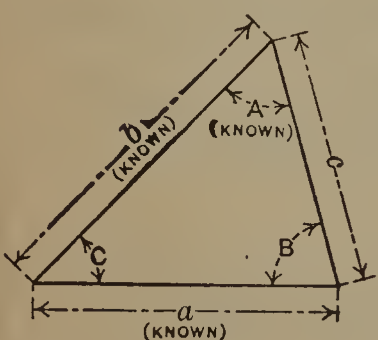
$$\tan A = \frac{a \times \sin C}{b - a \times \cos C}$$

$$B = 180^\circ - (A + C) \qquad c = \frac{a \times \sin C}{\sin A}$$

Side c may also be found directly as below:

$$c = \sqrt{a^2 + b^2 - 2\,ab \times \cos C}$$

$$\text{Area} = \frac{a \times b \times \sin C}{2}$$



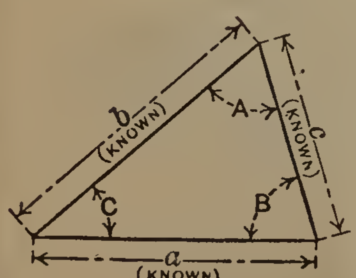
Two sides and the angle opposite one of the sides known.

Call the known angle A, the side opposite it a, and the other known side b. Then:

$$\sin B = \frac{b \times \sin A}{a} \qquad C = 180^\circ - (A + B)$$

$$c = \frac{a \times \sin C}{\sin A}$$

$$\text{Area} = \frac{a \times b \times \sin C}{2}$$



All three sides known.

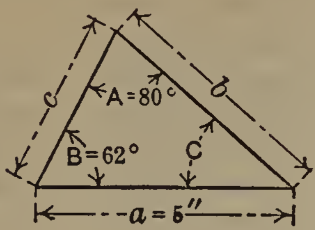
Call the sides a, b and c, and the angles opposite them, A, B and C. Then:

$$\cos A = \frac{b^2 + c^2 - a^2}{2\,bc}$$

$$\sin B = \frac{b \times \sin A}{a} \qquad C = 180^\circ - (A + B)$$

$$\text{Area} = \frac{a \times b \times \sin C}{2}$$

Examples of the Solution of Oblique-angled Triangles



Sides and angles known:

$$a = 5 \text{ inches};\; A = 80°;\; B = 62°.$$

Then, by the formulas on the opposite page:

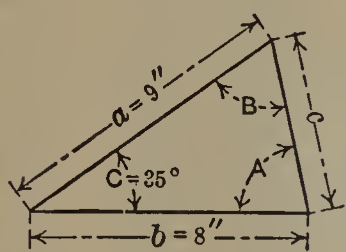
$$C = 180° - (80° + 62°) = 180° - 142° = 38°.$$

$$b = \frac{a \times \sin B}{\sin A} = \frac{5 \times \sin 62°}{\sin 80°} = \frac{5 \times 0.88295}{0.98481} = 4.483$$

inches.

$$c = \frac{a \times \sin C}{\sin A} = \frac{5 \times \sin 38°}{\sin 80°} = \frac{5 \times 0.61566}{0.98481} = 3.126$$

inches.



Sides and angles known:

$$a = 9 \text{ inches};\; b = 8 \text{ inches};\; C = 35°.$$

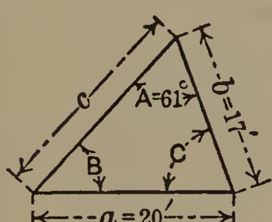
$$\tan A = \frac{a \times \sin C}{b - a \times \cos C} = \frac{9 \times \sin 35°}{8 - 9 \times \cos 35°}$$

$$= \frac{9 \times 0.57358}{8 - 9 \times 0.81915} = \frac{5.16222}{0.62765} = 8.22468.$$

Hence, $A = 83°\ 4'.$

$$B = 180° - (A + C) = 180° - 118°\ 4' = 61°\ 56'.$$

$$c = \frac{a \times \sin C}{\sin A} = \frac{9 \times 0.57358}{0.99269} = 5.2 \text{ inches}.$$



Sides and angles known:

$$a = 20 \text{ feet};\; b = 17 \text{ feet};\; A = 61°.$$

$$\sin B = \frac{b \times \sin A}{a} = \frac{17 \times \sin 61°}{20}$$

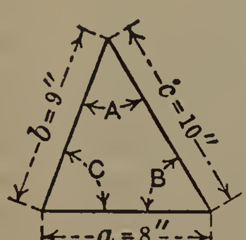
$$= \frac{17 \times 0.87462}{20} = 0.74343.$$

Hence, $B = 48°\ 1'.$

$$C = 180° - (A + B) = 180° - 109°\ 1' = 70°\ 59'.$$

$$c = \frac{a \times \sin C}{\sin A} = \frac{20 \times \sin 70°\ 59'}{\sin 61°} = \frac{20 \times 0.94542}{0.87462}$$

$$= 21.62 \text{ feet}.$$



Sides known:

$$a = 8 \text{ inches};\; b = 9 \text{ inches};\; c = 10 \text{ inches}.$$

$$\cos A = \frac{b^2 + c^2 - a^2}{2\,bc} = \frac{9^2 + 10^2 - 8^2}{2 \times 9 \times 10}$$

$$= \frac{81 + 100 - 64}{180} = \frac{117}{180} = 0.65000.$$

Hence, $A = 49°\ 27'.$

$$\sin B = \frac{b \times \sin A}{a} = \frac{9 \times 0.75984}{8} = 0.85482.$$

Hence, $B = 58°\ 44'.$

$$C = 180° - (A + B) = 180° - 108°\ 11' = 71°\ 49'.$$

Table for Converting Minutes into Decimals of a Degree

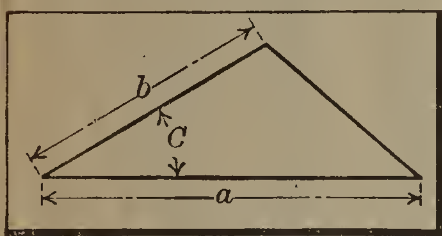
Use of Logarithms in Solving Triangles

The following tables "Logarithms of Trigonometrical Functions" may be used in the solution of triangles. The calculations are worked out in the same manner as with logarithms in general. In these tables, the characteristic is given in all cases, together with the mantissa. The complete logarithm of the functions, therefore, is found directly from the tables; however, as the values of the natural functions of sines and cosines, and of tangents for angles less than 45 degrees, are always less than 1, the characteristics would always be negative for these functions. In order to avoid these negative characteristics, the logarithm, as generally given, has had 10 added to its value; consequently, the actual value of the logarithm for "cosine 3 degrees," for example, is 9.99940 − 10.

When using these logarithms in calculations with other logarithms, the calculations can be carried out exactly as explained under "LOGARITHMS." When writing down the logarithm taken from the tables of "Logarithms of Trigonometrical Functions," $\bar{1}.99940$ is written for 9.99940, $\bar{2}.71940$ for 8.71940, $\bar{3}.30882$ for 7.30882, etc., changing the form to that which was made use of in the section on "LOGARITHMS." The examples which follow will show the method of procedure.



Example: — Find the area of a triangle where the lengths of two sides are 53 and 82 inches, and the angle between them is 30 degrees.

The area is found by the formula (see accompanying illustration):

$$\text{Area} = \frac{a \times b \times \sin C}{2} = \frac{53 \times 82 \times \sin 30^\circ}{2}$$

The logarithms of the numbers 53 and 82 are obtained from the regular tables in the usual manner. The logarithm for the sine of 30 degrees, as given in the table of "Logarithms of Trigonometrical Functions" is 9.69897 which, as previously explained, is written as $\bar{1}.69897$. The logarithm of the divisor is given a negative value, as explained in the section on "LOGARITHMS." (See "Division by Logarithms.") Proceed now to find the logarithm of the area.

$$\begin{aligned} \log 53 &= 1.72428 \\ \log 82 &= 1.91381 \\ \log \sin 30^\circ &= \bar{1}.69897 \\ -\log 2 &= \bar{1}.69897 \\ \hline &\quad 3.03603 \end{aligned}$$

The logarithm of the area thus is 3.03603, and from a logarithmic table it is found, by interpolation, that the area equals 1086.5 square inches.

Angles A and C and side a in a triangle are known. (See table "Solution of Oblique-angled Triangles.") $A = 37^\circ\ 42'$; $C = 68^\circ\ 12'$; $a = 12$ inches. Find side c.

The formula for finding side c is:

$$c = \frac{a \times \sin C}{\sin A} = \frac{12 \times \sin 68^\circ\ 12'}{\sin 37^\circ\ 42'}$$

When finding the logarithms, note that as log sine $37^\circ\ 42' = \bar{1}.78642$, the negative value of the logarithm equals 0.21358.

$$\begin{aligned} \log 12 &= 1.07918 \\ \log \sin 68^\circ\ 12' &= \bar{1}.96778 \\ -\log \sin 37^\circ\ 42' &= 0.21358 \\ \hline &\quad 1.26054 \end{aligned}$$

Thus $\log c = 1.26054$, and, hence, $c = 18.22$ inches.

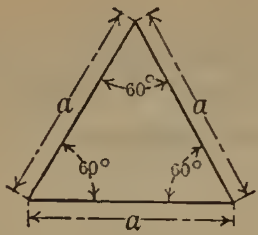
Geometrical Propositions

	The sum of the three angles in a triangle always equals 180 degrees. Hence, if two angles are known, the third angle can always be found. $A + B + C = 180°$ $\quad A = 180° - (B + C)$ $B = 180° - (A + C)$ $\quad C = 180° - (A + B)$
	If one side and two angles in one triangle are equal to one side and similarly located angles in another triangle, then the remaining two sides and angle are also equal. If $a = a_1$, $A = A_1$ and $B = B_1$, then the two other sides and the remaining angle are also equal.
	If two sides and the angle between them in one triangle are equal to two sides and a similarly located angle in another triangle, then the remaining side and angles are also equal. If $a = a_1$, $b = b_1$ and $A = A_1$, then the remaining side and angles are also equal.
	If the three sides in one triangle are equal to the three sides of another triangle, then the angles in the two triangles are also equal. If $a = a_1$, $b = b_1$ and $c = c_1$, then the angles between the respective sides are also equal.
	If the three sides of one triangle are proportional to corresponding sides in another triangle, then the triangles are called *similar*, and the angles in the one are equal to the angles in the other. If $a : b : c = d : e : f$, then $A = D$, $B = E$ and $C = F$.
	If the angles in one triangle are equal to the angles of another triangle, then the triangles are similar and their corresponding sides are proportional. If $A = D$, $B = E$ and $C = F$, then $a : b : c = d : e : f$.

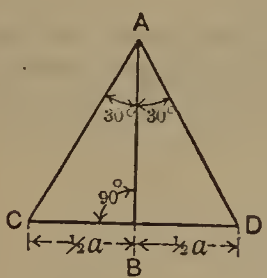
Geometrical Propositions



If the three sides in a triangle are equal — that is, if the triangle is *equilateral* — then the three angles are also equal.

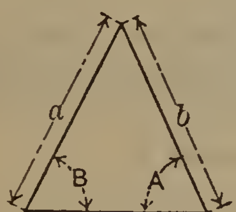
Each of the three equal angles in an equilateral triangle is 60 degrees.

If the three angles in a triangle are equal, then the three sides are also equal.



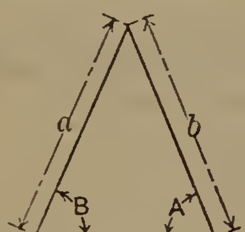
A line which in an equilateral triangle bisects or divides any of the angles into two equal parts, bisects also the side opposite the angle and is at right angles to it.

If line AB divides angle CAD into two equal parts, it also divides line CD into two equal parts and is at right angles to it.



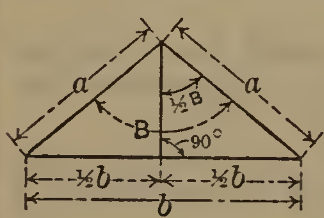
If two sides in a triangle are equal — that is, if the triangle is an *isosceles* triangle — then the angles opposite these sides are also equal.

If side a equals side b, then angle A equals angle B.

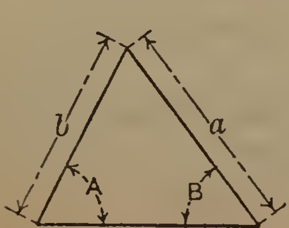


If two angles in a triangle are equal, then the sides opposite these angles are also equal.

If angles A and B are equal, then side a equals side b.



In an isosceles triangle, if a straight line is drawn from the point where the two equal sides meet, so that it bisects the third side or base of the triangle, then it also bisects the angle between the equal sides and is perpendicular to the base.



In every triangle, that angle is greater which is opposite a longer side. — In every triangle, that side is greater which is opposite a greater angle.

If a is longer than b, then angle A is greater than B. If angle A is greater than B, then side a is longer than b.

Geometrical Propositions

	In every triangle, the sum of the lengths of two sides is always greater than the length of the third. Side $a +$ side b is always greater than side c.
	In a right-angled triangle, the square of the hypotenuse or the side opposite the right angle is equal to the sum of the squares on the two sides which form the right angle. $a^2 = b^2 + c^2$.
	If one side of a triangle is produced, then the exterior angle is equal to the sum of the two interior opposite angles. Angle $D =$ angle $A +$ angle B.
	If two lines intersect, then the opposite angles formed by the intersecting lines are equal. Angle $A =$ angle B. Angle $C =$ angle D.
	If a line intersects two parallel lines, then the corresponding angles formed by the intersecting line and the parallel lines are equal. Lines ab and cd are parallel. Then all the angles designated A are equal, and all those designated B are equal.
	In any figure having four sides, the sum of the interior angles equals 360 degrees. $A + B + C + D = 360$ degrees.

Geometrical Propositions

	The sides which are opposite each other in a parallelogram are equal; the angles which are opposite each other are equal; the diagonal divides it into two equal parts. If two diagonals are drawn, they bisect each other.
	The areas of two parallelograms which have equal base and equal height, are equal. If $a = a_1$ and $h = h_1$, then area A = area A_1.
	The areas of triangles having equal base and equal height are equal. If $a = a_1$ and $h = h_1$, then area A = area A_1.
	If a diameter of a circle is at right angles to a chord, then it bisects or divides the chord into two equal parts.
	If a line is tangent to a circle, then it is also at right angles to a line drawn from the center of the circle to the point of tangency — that is, to a radial line through the point of tangency.
	If two circles are tangent to each other, then the straight line which passes through the centers of the two circles must also pass through the point of tangency.

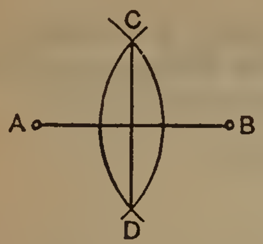
Geometrical Propositions

	If from a point without a circle tangents are drawn to a circle, the two tangents are equal and make equal angles with the chord joining the points of tangency.
	The angle between a tangent and a chord drawn from the point of tangency equals one-half the angle at the center subtended by the chord. Angle $B = \frac{1}{2}$ angle A.
	The angle between a tangent and a chord drawn from the point of tangency equals the angle at the periphery subtended by the chord. Angle B, between tangent ab and chord cd, equals angle A subtended at the periphery by chord cd.
	All angles having their vertex at the periphery of a circle and subtended by the same chord are equal. Angles A, B and C, all subtended by chord cd, are equal.
	If an angle at the circumference of a circle, between two chords, is subtended by the same arc as the angle at the center, between two radii, then the angle at the circumference is equal to one-half of the angle at the center. Angle $A = \frac{1}{2}$ angle B.
A=LESS THAN 90° B=MORE THAN 90° 	An angle subtended by a chord in a circular segment larger than one-half the circle is an acute angle — an angle less than 90 degrees. An angle subtended by a chord in a circular segment less than one-half the circle is an obtuse angle — an angle greater than 90 degrees.

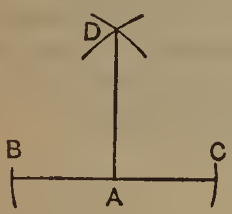
Geometrical Propositions

	If two chords intersect each other in a circle, then the rectangle of the segments of the one equals the rectangle of the segments of the other. $a \times b = c \times d.$
	If from a point outside of a circle two lines are drawn, one of which intersects the circle while the other is tangent to it, then the rectangle contained by the total length of the intersecting line, and that part of it which is between the outside point and the periphery, equals the square of the tangent. $a^2 = b \times c.$
	If a triangle is inscribed in a semi-circle, the angle opposite the diameter is a right (90-degree) angle. All angles at the periphery of a circle, subtended by the diameter, are right (90-degree) angles.
	The length of circular arcs of the same circle are proportional to the corresponding angles at the center. $A : B = a : b.$
	The length of circular arcs having the same center angle are proportional to the length of the radii. If $A = B$, then $a : b = r : R.$
	The circumferences of two circles are proportional to their radii. The areas of two circles are proportional to the squares of their radii. $c : C = r : R.$ $a : A = r^2 : R^2.$

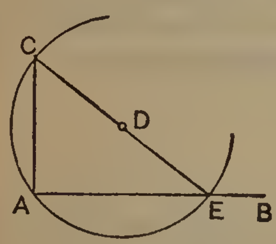
Geometrical Problems



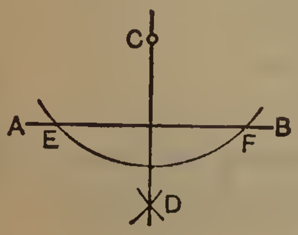
To divide a line AB into two equal parts: With the ends A and B as centers and a radius greater than one-half the line, draw circular arcs. Through the intersections C and D, draw line CD. This line divides AB into two equal parts and is also perpendicular to AB.



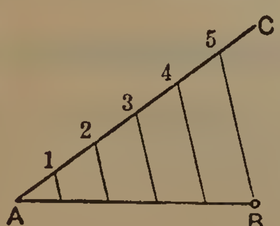
To draw a perpendicular to a straight line from a point A on that line: With A as a center and with any radius, draw circular arcs intersecting the given line at B and C. Then, with B and C as centers and a radius longer than AB, draw circular arcs intersecting at D. Line DA is perpendicular to BC at A.



To draw a perpendicular line from a point A at the end of a line AB: With any point D, outside of the line AB, as a center, and with AD as a radius, draw a circular arc intersecting AB at E. Draw a line through E and D intersecting the arc at C; then join AC. This line is the required perpendicular.

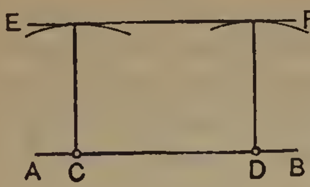


To draw a perpendicular to a line AB from a point C at a distance from it: With C as a center, draw a circular arc intersecting the given line at E and F. With E and F as centers, draw circular arcs with a radius longer than one-half the distance between E and F. These arcs intersect at D. Line CD is the required perpendicular.

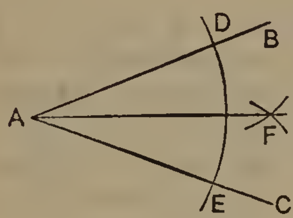


To divide a straight line AB into a number of equal parts: Let it be required to divide AB into five equal parts. Draw line AC at an angle with AB. Set off on AC five equal parts of any convenient length. Draw $B\,5$ and then draw lines parallel with $B\,5$ through the other division points on AC. The points where these lines intersect AB are the required division points.

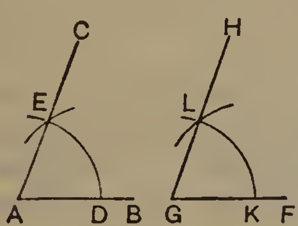
Geometrical Problems



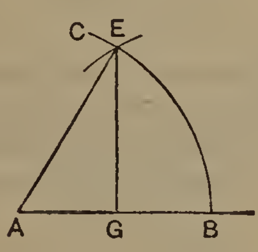
To draw a straight line parallel to a given line AB, at a given distance from it: With any points C and D on AB as centers, draw circular arcs with the given distance as radius. Line EF, drawn to touch the circular arcs, is the required parallel line.



To bisect or divide an angle BAC into two equal parts: With A as a center and any radius, draw arc DE. With D and E as centers and a radius greater than one-half DE, draw circular arcs intersecting at F. Line AF divides the angle into two equal parts.

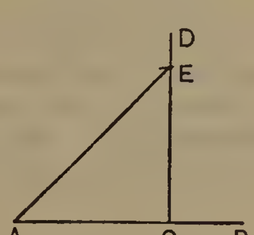


To draw an angle upon a line AB, equal to a given angle FGH: With point G as a center and with any radius, draw arc KL. With A as a center and with the same radius, draw arc DE. Make arc DE equal to KL and draw AC through E. Angle BAC then equals angle FGH.

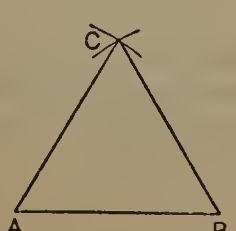


To lay out a 60-degree angle: With A as a center and any radius, draw an arc BC. With point B as a center and AB as a radius, draw an arc intersecting at E the arc just drawn. EAB is a 60-degree angle.

A 30-degree angle may be obtained either by dividing a 60-degree angle into two equal parts, or by drawing a line EG perpendicular to AB. Angle AEG is then 30 degrees.

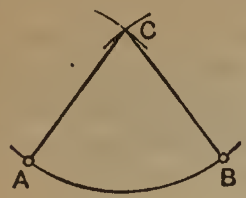


To draw a 45-degree angle: From point A on line AB set off a distance AC. Draw the perpendicular DC and set off a distance CE equal to AC. Draw AE. Angle EAC is a 45-degree angle.

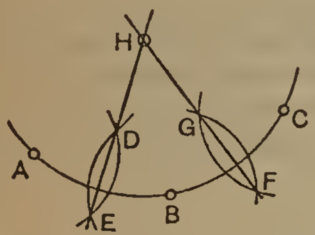


To draw an equilateral triangle, the length of the sides of which equals AB: With A and B as centers and AB as radius, draw circular arcs intersecting at C. Draw AC and BC. Then ABC is an equilateral triangle.

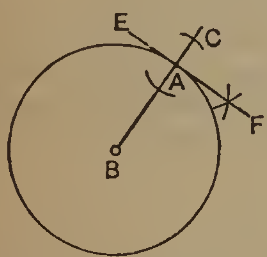
Geometrical Problems



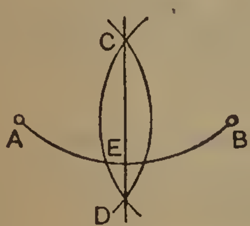
To draw a circular arc with a given radius through two given points A and B: With A and B as centers, and the given radius as radius, draw circular arcs intersecting at C. With C as a center, and the same radius, draw a circular arc through A and B.



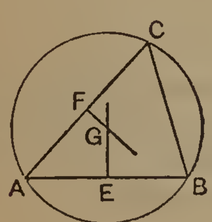
To find the center of a circle or of an arc of a circle: Select three points on the periphery of the circle, as A, B and C. With each of these points as a center and the same radius, describe arcs intersecting each other. Through the points of intersection draw lines DE and FG. Point H where these lines intersect is the center of the circle.



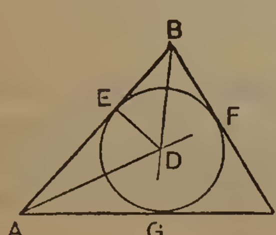
To draw a tangent to a circle from a given point on the circumference: Through the point of tangency A, draw a radial line BC. At point A, draw a line EF at right angles to BC. This line is the required tangent.



To divide a circular arc AB into two equal parts: With A and B as centers, and a radius larger than half the distance between A and B, draw circular arcs intersecting at C and D. Line CD divides arc AB into two equal parts at E.

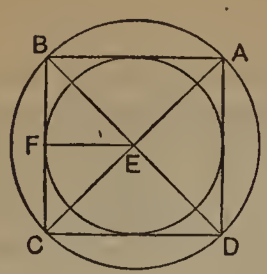


To describe a circle about a triangle: Divide the sides AB and AC into two equal parts, and from the division points E and F draw lines at right angles to the sides. These lines intersect at G. With G as a center and GA as a radius, draw circle ABC.

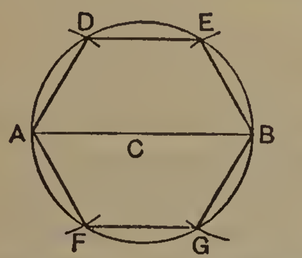


To inscribe a circle in a triangle: Bisect two of the angles, A and B, by lines intersecting at D. From D draw a line DE perpendicular to one of the sides, and with DE as a radius, draw circle EFG.

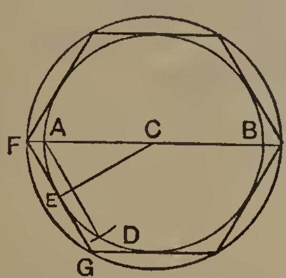
Geometrical Problems



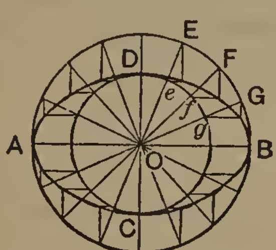
To describe a circle about a square and to inscribe a circle in a square: The center of both the circumscribed and inscribed circle is located at the point *E*, where the two diagonals of the square intersect. The radius of the circumscribed circle is *AE*, and of the inscribed circle, *EF*.



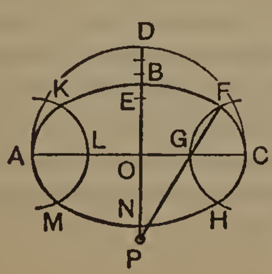
To inscribe a hexagon in a circle: Draw a diameter *AB*. With *A* and *B* as centers and with the radius of the circle as radius, describe circular arcs intersecting the given circle at *D*, *E*, *F* and *G*. Draw lines *AD*, *DE*, etc., forming the required hexagon.



To describe a hexagon about a circle: Draw a diameter *AB*, and with *A* as a center and the radius of the circle as radius, cut the circumference of the given circle at *D*. Join *AD* and bisect it with radius *CE*. Through *E*, draw *FG* parallel to *AD* and intersecting line *AB* at *F*. With *C* as a center and *CF* as radius, draw a circle. Within this circle inscribe the hexagon as in the preceding problem.

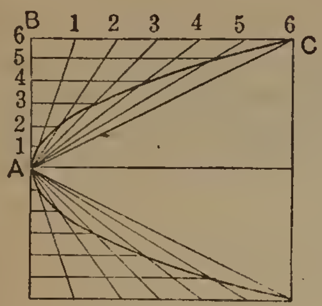


To describe an ellipse with the given axes *AB* and *CD*: Describe circles with *O* as a center and *AB* and *CD* as diameters. From a number of points, *E*, *F*, *G*, etc., on the outer circle draw radii intersecting the inner circle at *e*, *f*, *g*. From *E*, *F* and *G* draw lines perpendicular to *AB*, and from *e*, *f* and *g* draw lines parallel to *AB*. The intersections of these perpendicular and parallel lines are points on the curve of the ellipse.

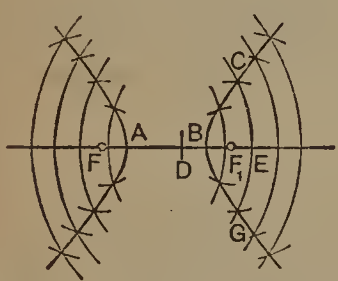


To construct an approximate ellipse by circular arcs: Let *AC* be the major axis and *BN* the minor. Draw half circle *ADC* with *O* as a center. Divide *BD* into three equal parts and set off *BE* equal to one of these parts. With *A* and *C* as centers and *OE* as radius, describe circular arcs *KLM* and *FGH*; with *G* and *L* as centers, and the same radius, describe arcs *FCH* and *KAM*. Through *F* and *G* draw line *FP*, and with *P* as a center draw the arc *FBK*. Arc *HNM* is drawn in the same manner.

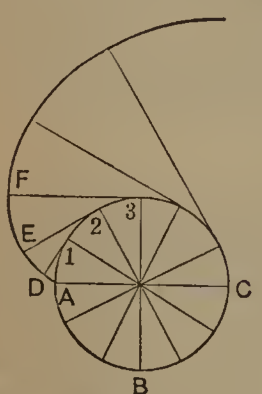
Geometrical Problems



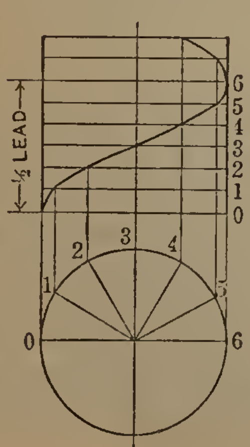
To construct a parabola: Divide line AB into a number of equal parts and divide BC into the same number of parts. From the division points on AB draw horizontal lines. From the division points on BC draw lines to point A. The points of intersection between lines drawn from points numbered alike are points on the parabola.



To construct a hyperbola: From focus F lay off a distance FD equal to the transverse axis, or the distance AB between the two branches of the curve. With F as a center and any distance FE greater than FB as a radius, describe a circular arc. Then with F_1 as a center and DE as a radius, describe arcs intersecting at C and G the arc just described. C and G are points on the hyperbola. Any number of points can be found in a similar manner.



To construct an involute: Divide the circumference of the base circle ABC into a number of equal parts. Through the division points 1, 2, 3, etc., draw tangents to the circle and make the lengths D 1, E 2, F 3, etc., of these tangents equal to the actual length of the arcs A 1, A 2, A 3, etc.



To construct a helix: Divide half the circumference of the cylinder on the surface of which the helix is to be described into a number of equal parts. Divide half the lead of the helix into the same number of equal parts. From the division points on the circle representing the cylinder draw vertical lines, and from the division points on the lead draw horizontal lines as shown. The intersections between lines numbered alike are points on the helix.

MECHANICS

Mechanics treats of the action of forces and their effect. A *force* is defined as any cause tending to produce or modify motion. The units by which a force is usually measured are pounds or tons. Besides force there are two other elementary quantities in mechanics from which numerous compound quantities are derived. These are *distance*, measured in linear units, as inches, feet, etc., and *time*, expressed in hours, minutes or seconds.

Work, in mechanics, is the product of force by distance, and is expressed by a combination of units of weight (force) and distance, as inch-pounds, foot-pounds, foot-tons, etc.

Power, in mechanics, is the product of force by distance divided by time, or the performance of a given amount of work in a given time, and is expressed as inch-pounds per minute, foot-pounds per minute or second, etc.

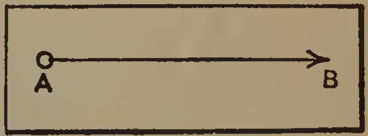
The term *power* is frequently used by writers on mechanics to designate a *force*. In connection with the so-called "mechanical powers" — the lever, wheel and axle, wedge, screw, etc. — it is usual to speak of the applied force as the power; this is, however, not strictly correct, as power should always, in mechanics, be used in accordance with the definition given above.

Horsepower (abbreviated H.P.) is the unit of power adopted for engineering work. One horsepower is equal to 33,000 foot-pounds per minute, or 550 foot-pounds per second. The metric horsepower, used in countries where the metric system is employed, is equal to 75 kilogram-meters per second, or 542.5 foot-pounds per second, or 32,550 foot-pounds per minute. The *kilowatt*, used in electrical work, equals 1.34 horsepower; or one horsepower equals 0.746 kilowatt.

Velocity is distance divided by time, and is expressed in feet per minute, miles per hour, etc.

Inertia is that property of a body which causes it to tend to continue in its present state of rest or motion, unless acted upon by some force.

Graphical Representation of Forces. — A force has three characteristics which, when known, determine it. They are direction, place of application, and magnitude. The *direction* of a force is the direction in which it tends to move the body upon which it acts. The *place of application* is generally assumed to be a point, as the center of gravity. The *magnitude* is measured in pounds, as already stated. Forces may conveniently be represented by straight lines and arrow heads. The arrow head indicates the direction of the force, and the length of the line its magnitude to any suitable scale. The point of application may be at any point on the line, but it is generally convenient to assume it to be at one end. In the accompanying

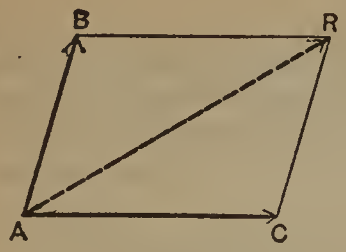


illustration, a force is supposed to act along line AB in a direction from left to right. The length of line AB shows the magnitude of the force. If point A is the point of application, the force is exerted as a pull, but if point B be assumed to be the point of application, it would indicate that the force is exerted as a push.

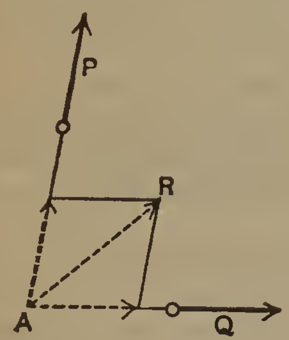
The single force which produces the same effect upon a body as two or more forces acting together, is called their *resultant*. The separate forces which can be so combined are called the *components*. The finding of the resultant of two or more forces is called the *composition* of forces, and the finding of two or more components of a given force, the *resolution* of forces.

On the two following pages are shown the methods used in the solution of those problems in the composition of forces that are most frequently met with. The resolution of forces is carried out in a similar manner to the composition, except that the work is carried out in a reverse order.

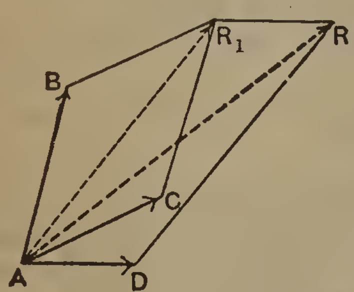
Composition and Resolution of Forces



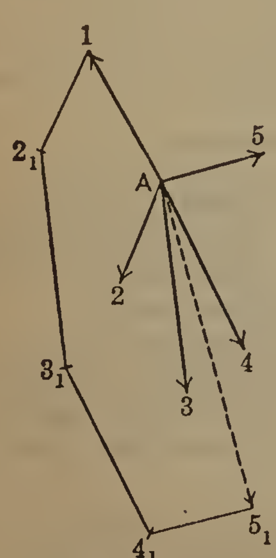
Parallelogram of Forces. — If two forces applied at a point are represented in magnitude and direction by the adjacent sides of a parallelogram (AB and AC in the accompanying illustration), their resultant will be represented in magnitude and direction by the diagonal AR drawn from the intersection of the two component forces.



If two forces P and Q do not have the same point of application, but the lines indicating their directions intersect, the forces may be imagined as applied at the point of intersection between the lines (as at A), and the resultant of the two forces may be found by constructing the parallelogram of forces. Line AR shows the direction and magnitude of the resultant, the point of application of which may be assumed to be at any point on line AR or its extension.

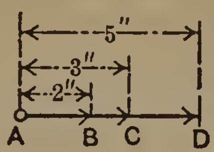


If the resultant of three or more forces having the same point of application is to be found, first find the resultant of any two of the forces (AB and AC) and then find the resultant of the resultant just found (AR_1) and the third force (AD). If there be more than three forces, continue in this manner until the resultant of all the forces has been found.

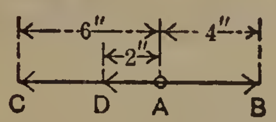


Polygon of Forces. — When several forces are applied at a point and act in a single plane, their resultant may be found more simply than by the method just described, as follows: From the extreme end of the line representing the first force, draw a line representing the second force, parallel to it and of the same length and in the direction of the second force. Then through the extreme end of this line draw a line parallel to, and of the same length and direction as the third force, and continue this until all the forces have been thus represented. Then draw a line from the point of application of the forces (as A) to the extreme point (as 5_1) of the line last drawn. This line ($A\ 5_1$) is the resultant of the forces.

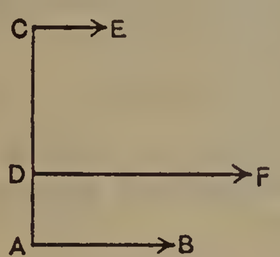
Composition and Resolution of Forces



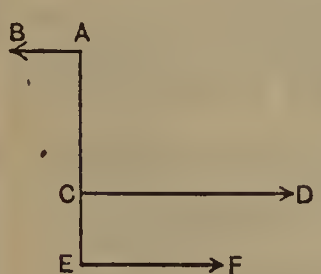
The resultant of two forces applied at the same point and acting in the same direction, is equal to the sum of the forces. For example, if the two forces AB and AC, one equal to two and the other equal to three pounds, are applied at point A, then their resultant AD equals the sum of these forces, or five pounds.



If two forces act in opposite directions, then their resultant is equal to their difference, and the direction of the resultant is the same as the direction of the greater of the two forces. For example: AB and AC are both applied at point A; then, if AB equals four and AC equals six pounds, the resultant AD equals two pounds and acts in the direction of AC.

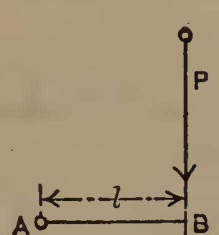


Parallel Forces. — If two forces are parallel and act in the same direction, then their resultant is parallel to both lines, is located between them, and is equal to the sum of the two components. The point of application of the resultant divides the line joining the points of application of the components inversely as the magnitude of the components. Thus, $AB:CE = CD:AD$.



The resultant of two parallel forces acting in opposite directions is parallel to both lines, is located outside of them on the side of the greater of the components, has the same direction as the greater component, and is equal in magnitude to the difference between the two components. The point of application on the line AC produced is found from the proportion:

$$AB : CD = CE : AE.$$



Moment of P about A Equals $P \times l$

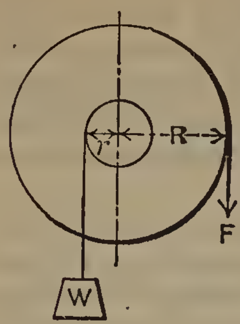
Moment of a Force. — The moment of a force with respect to a point is the product of the force multiplied by the perpendicular distance from the given point to the direction of the force. In the illustration, the moment of the force P with relation to point A is $P \times AB$. The perpendicular distance AB is called the lever-arm of the force. The moment is the measure of the tendency of the force to produce rotation about the given point, which is termed the center of moments. If the force is measured in pounds and the distance in inches, the moment is expressed in inch-pounds.

The moment of the resultant of any number of forces acting together in the same plane is equal to the algebraic sum of the moments of the separate forces.

Levers

Types of Levers	Examples
 $F:W=l:L \qquad F\times L=W\times l$ $F=\frac{W\times l}{L} \qquad W=\frac{F\times L}{l}$ $L=\frac{W\times a}{W+F}=\frac{W\times l}{F};\quad l=\frac{F\times a}{W+F}=\frac{F\times L}{W}$	A pull of 80 pounds is exerted at the end of the lever, at W; $l=12$ inches and $L=32$ inches. Find the value of force F required to balance the lever. $F=\frac{80\times 12}{32}=\frac{960}{32}=30$ pounds. If $F=20$; $W=180$; and $l=3$; how long must L be made to secure equilibrium? $L=\frac{180\times 3}{20}=27.$
 $F:W=l:L \qquad F\times L=W\times l$ $F=\frac{W\times l}{L} \qquad W=\frac{F\times L}{l}$ $L=\frac{W\times a}{W-F}=\frac{W\times l}{F};\quad l=\frac{F\times a}{W-F}=\frac{F\times L}{W}$	Total length L of a lever is 25 inches. A weight of 90 pounds is supported at W; l is 10 inches. Find the value of F. $F=\frac{90\times 10}{25}=36$ pounds. If $F=100$ pounds, $W=2200$ pounds, and $a=5$ feet, what should L equal to secure equilibrium? $L=\frac{2200\times 5}{2200-100}=5.24$ feet.
 $F:W=l:L \qquad F\times L=W\times l$ $F=\frac{W\times l}{L} \qquad W=\frac{F\times L}{l}$ $L=\frac{W\times a}{F-W}=\frac{W\times l}{F};\quad l=\frac{F\times a}{F-W}=\frac{F\times L}{W}$	$F=28$ pounds; $L=10$ inches; $a=24$ inches. What weight W can be supported? $l=a+L=24+10=34$ inches. $W=\frac{28\times 10}{34}=8.23$ pounds. Let $F=12$ tons; $W=4.5$ tons; $a=16$ feet. Find L and l. $L=\frac{4.5\times 16}{12-4.5}=9.6$ feet; $l=16+9.6=25.6$ feet.
 When three or more forces act on a lever: $F\times x=W\times a+P\times b+Q\times c$ $x=\frac{W\times a+P\times b+Q\times c}{F}$ $F=\frac{W\times a+P\times b+Q\times c}{x}$	Let $W=20$, $P=30$, and $Q=15$ pounds; $a=4$, $b=7$, and $c=10$ inches. If $x=6$ inches, find F. $F=\frac{20\times 4+30\times 7+15\times 10}{6}=73\frac{1}{3}$ lbs. Assuming $F=20$ in the example above, how long must lever arm x be made? $x=\frac{20\times 4+30\times 7+15\times 10}{20}=22$ ins.

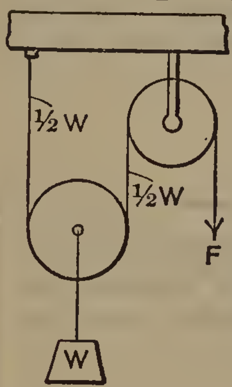
Wheels and Pulleys



$$F : W = r : R$$
$$F \times R = W \times r$$
$$F = \frac{W \times r}{R}$$
$$W = \frac{F \times R}{r}$$
$$R = \frac{W \times r}{F}$$
$$r = \frac{F \times R}{W}$$

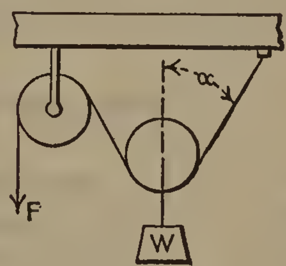
The radius of a drum on which is wound the lifting rope of a windlass is 2 inches. What force will be exerted at the periphery of a gear of 24 inches diameter, mounted on the same shaft as the drum and transmitting power to it, if one ton (2000 pounds) is to be lifted? Here $W = 2000$; $R = 12$; $r = 2$.

$$F = \frac{2000 \times 2}{12} = 333 \text{ pounds.}$$

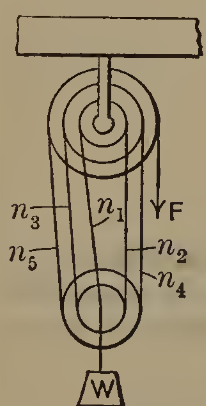


$$F = \tfrac{1}{2} W$$

The velocity with which weight W will be raised equals one-half the velocity of the force applied at F.



$$F : W = \sec \alpha : 2$$
$$F = \frac{W \times \sec \alpha}{2}$$
$$W = 2F \times \cos \alpha$$



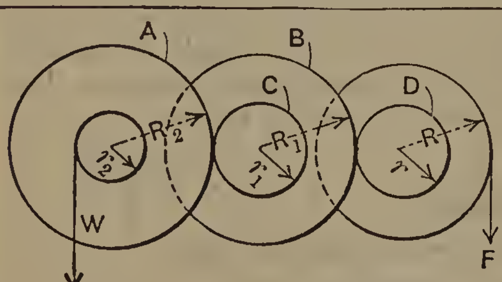
n = number of strands or parts of rope (n_1, n_2, etc.).

$$F = \frac{1}{n} \times W$$

The velocity with which W will be raised equals $\frac{1}{n}$ of the velocity of the force applied at F.

In the illustration is shown a combination of a double and triple block. The pulleys each turn freely on a pin as axis, and are drawn with different diameters, to show the parts of the rope more clearly. There are 5 parts of rope. Therefore, if 200 pounds is to be lifted, the force F required at the end of the rope is:

$$F = \tfrac{1}{5} \times 200 = 40 \text{ pounds.}$$



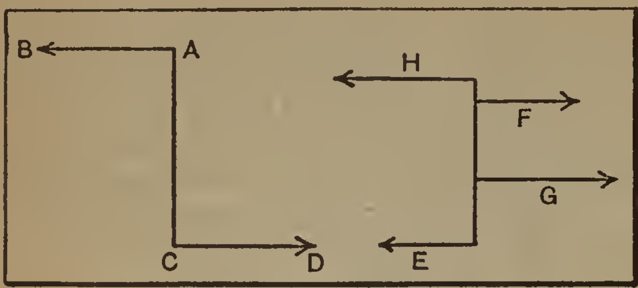
A, *B*, *C* and *D* are the pitch circles of gears.

$$F = \frac{W \times r \times r_1 \times r_2}{R \times R_1 \times R_2}$$
$$W = \frac{F \times R \times R_1 \times R_2}{r \times r_1 \times r_2}$$

Let the pitch diameters of gears A, B, C and D be 30, 28, 12 and 10 inches, respectively. Then $R_2 = 15$; $R_1 = 14$; $r_1 = 6$; and $r = 5$. Let $R = 12$, and $r_2 = 4$. Then the force F required to lift a weight W of 2000 pounds, friction being neglected, is:

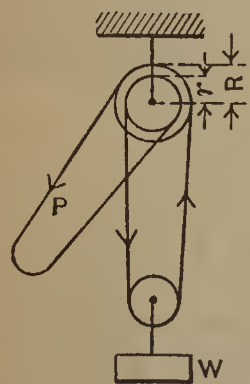
$$F = \frac{2000 \times 5 \times 6 \times 4}{12 \times 14 \times 15} = 95 \text{ pounds.}$$

Couples. — If the forces AB and CD are equal and act in opposite directions, then the resultant equals o, or, in other words, the two forces have no resultant and are called a couple. A couple tends to produce rotation. The measure of this tendency is called the moment of the couple and is the product of one of the forces multiplied by the distance between the two.



As a couple has no resultant, no single force can balance or counteract the tendency of the couple to produce rotation. To prevent the rotation of a body acted upon by a couple, two other forces are therefore required, forming a second couple. In the illustration, E and F form one couple and G and H are the balancing couple. The body on which they act is in equilibrium if the moments of the two couples are equal and tend to rotate the body in opposite directions.

Differential Pulley — Screw

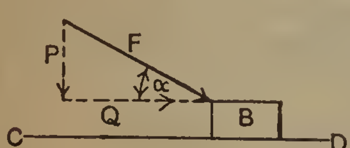


Differential Pulley. — In the differential pulley a chain must be used, engaging sprockets, so as to prevent the chain from slipping over the pulley faces.

$$P \times R = \tfrac{1}{2} W (R - r)$$

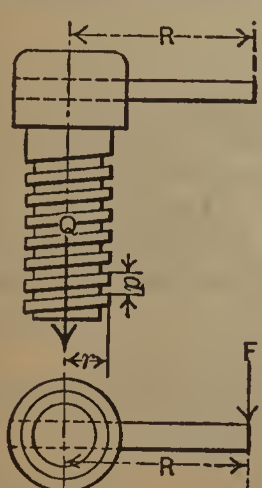
$$P = \frac{W (R - r)}{2 R}$$

$$W = \frac{2 PR}{R - r}$$



Force Moving Body on Horizontal Plane. — F tends to move B along line CD; Q is the component which actually moves B; P is the pressure, due to F, of the body on CD.

$$Q = F \times \cos\alpha; \qquad P = \sqrt{F^2 - Q^2}$$



Screw. — F = force at end of handle or wrench; R = lever-arm of F; r = pitch radius of screw; p = lead of thread. Then, neglecting friction:

$$F = Q \times \frac{p}{6.2832\,R} \qquad Q = F \times \frac{6.2832\,R}{p}$$

If μ is the coefficient of friction, then:

For motion in same direction as Q:

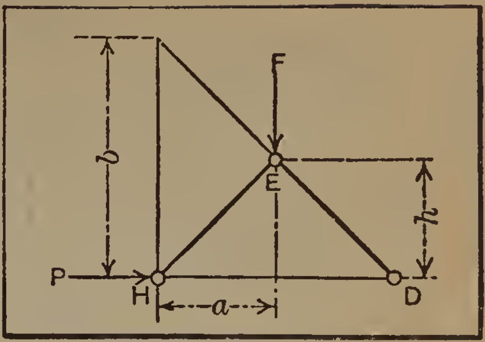
$$F = Q \times \frac{p - 6.2832\,\mu r}{6.2832\,r + \mu p} \times \frac{r}{R}$$

For motion in a direction opposite to Q:

$$F = Q \times \frac{p + 6.2832\,\mu r}{6.2832\,r - \mu p} \times \frac{r}{R}$$

Toggle-joint. — If arms ED and EH are of unequal length:

$$P = \frac{Fa}{b}$$



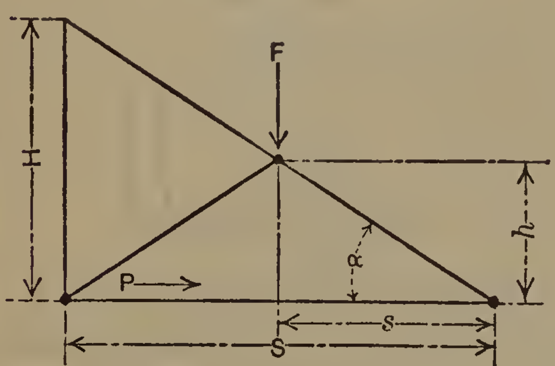
The relation between P and F changes constantly as F moves downwards.

If arms ED and EH are equal:

$$P = \frac{Fa}{2h}$$

A double toggle-joint does not increase the pressure exerted so long as the relative distances moved by F and P remain the same.

Toggle-joints with Equal Arms



F = power applied;
P = resistance;
α = given angle.

$$2P\sin\alpha = F\cos\alpha;$$

$$\frac{P}{F} = \frac{\cos\alpha}{2\sin\alpha} = \text{coefficient};$$

or, $P = F \times \text{coefficient}$.

Equivalent expressions:

$$P = \frac{FS}{4h}; \qquad P = \frac{Fs}{H}, \text{ as per diagram.}$$

To use the table, measure angle α, and find the coefficient in the table corresponding to the angle found. The coefficient is the ratio of the resistance to the power, and multiplying the power by the coefficient gives the resistance, neglecting friction.

Angle	Coefficient	Angle	Coefficient	Angle	Coefficient	Angle	Coefficient
0° 2′	862	0° 50′	34.4	2° 45′	10.4	8° 0′	3.58

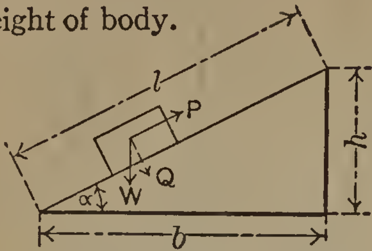
0 45	38.2	2 40	10.7	7 30	3.79	....	....

Inclined Plane — Wedge

W = weight of body.



Neglecting friction:

$$P = W \times \frac{h}{l} = W \times \sin\alpha$$

$$W = P \times \frac{l}{h} = \frac{P}{\sin\alpha} = P \times \operatorname{cosec}\alpha$$

$$Q = W \times \frac{b}{l} = W \times \cos\alpha$$

If friction is taken into account, then force P to pull body up is:

$$P = W\,(\mu\cos\alpha + \sin\alpha)$$

Force P_1 to pull body down is:

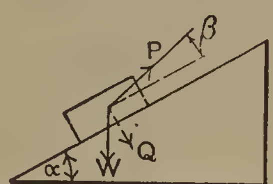
$$P_1 = W\,(\mu\cos\alpha - \sin\alpha)$$

Force P_2 to hold body stationary:

$$P_2 = W\,(\sin\alpha - \mu\cos\alpha)$$

in which μ is the coefficient of friction.

W = weight of body.



Neglecting friction:

$$P = W \times \frac{\sin\alpha}{\cos\beta}$$

$$W = P \times \frac{\cos\beta}{\sin\alpha}$$

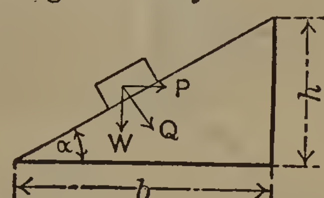
$$Q = W \times \frac{\cos(\alpha+\beta)}{\cos\beta}$$

With friction:

Coefficient of friction = $\mu = \tan\phi$.

$$P = W \times \frac{\sin(\alpha+\phi)}{\cos(\beta-\phi)}$$

W = weight of body.



Neglecting friction:

$$P = W \times \frac{h}{b} = W \times \tan\alpha$$

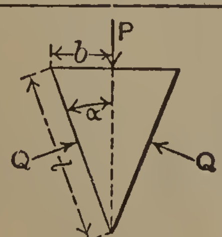
$$W = P \times \frac{b}{h} = P \times \cot\alpha$$

$$Q = \frac{W}{\cos\alpha} = W \times \sec\alpha$$

With friction:

Coefficient of friction = $\mu = \tan\phi$.

$$P = W\tan(\alpha+\phi)$$



Neglecting friction:

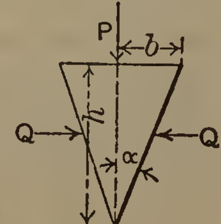
$$P = 2Q \times \frac{b}{l} = 2Q \times \sin\alpha$$

$$Q = P \times \frac{l}{2b} = \tfrac{1}{2}P \times \operatorname{cosec}\alpha$$

With friction:

Coefficient of friction = μ.

$$P = 2Q\,(\mu\cos\alpha + \sin\alpha)$$



Neglecting friction:

$$P = 2Q \times \frac{b}{h} = 2Q \times \tan\alpha$$

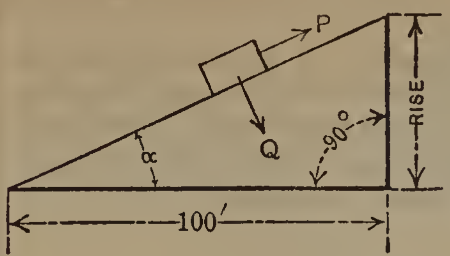
$$Q = P \times \frac{h}{2b} = \tfrac{1}{2}P \times \cot\alpha$$

With friction:

Coefficient of friction = $\mu = \tan\phi$.

$$P = 2Q\tan(\alpha+\phi)$$

Table of Forces on Inclined Planes



The table below makes it possible to find the force required for moving a body on an inclined plane. The friction on the plane is not taken into account. The column headed "Tension *P* in Cable per Ton of 2000 Pounds" gives the pull in pounds required for moving one ton along the inclined surface. The fourth column gives the perpendicular or normal pressure. If the coefficient of friction is known, the added pull required to overcome friction is thus easily determined:

$Q \times$ coefficient of friction = additional pull required.

Tensions and Pressures in Pounds

Per Cent of Grade. Rise, Ft. per 100 Ft.	Angle α	Tension P in Cable per Ton of 2000 Lbs.	Perpendicular Pressure Q on Plane per Ton of 2000 Lbs.	Per Cent of Grade. Rise, Ft. Per 100 Ft.	Angle α	Tension P in Cable per Ton of 2000 Lbs.	Perpendicular Pressure Q on Plane per Ton of 2000 Lbs.
1	0° 35′	20.2	1999.8	39	21° 19′	727.0	1863.0

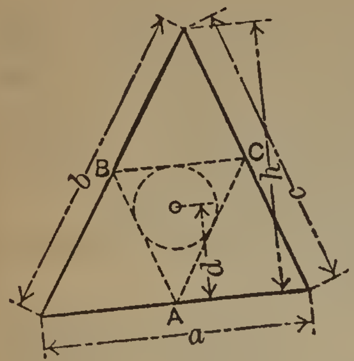
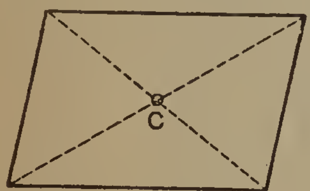
Center of Gravity



Perimeter of a Triangle. — If A, B and C are the middle points of the sides of the triangle, then the center of gravity is at the center of the circle that can be inscribed in triangle ABC. The distance d of the center of gravity from side a is:

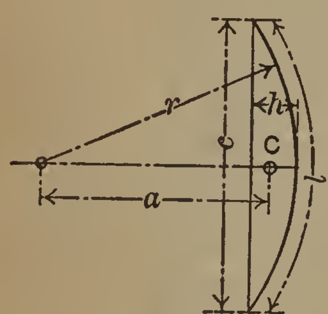
$$d = \frac{h\,(b + c)}{2\,(a + b + c)}$$

where h is the height perpendicular to a.



Perimeter of a Parallelogram. — The center of gravity is at the intersection of the diagonals.

Area of a Parallelogram. — The center of gravity is at the intersection of the diagonals.



Circular Arc. — The center of gravity is on the line that bisects the arc, at a distance

$$a = \frac{r \times c}{l} = \frac{c\,(c^2 + 4\,h^2)}{8\,lh}$$ from the center of the circle.

For an arc equal to one-half the periphery:

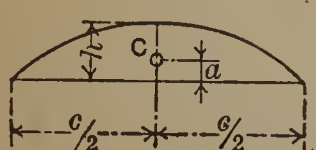
$$a = 2\,r \div \pi = 0.6366\,r$$

For an arc equal to one-quarter of the periphery:

$$a = 2\,r\sqrt{2} \div \pi = 0.9003\,r$$

For an arc equal to one-sixth of the periphery:

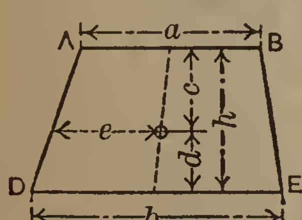
$$a = 3\,r \div \pi = 0.9549\,r$$

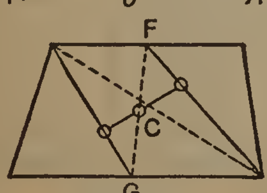


Circular Arc (approximate). —

$$a = \tfrac{2}{3}\,h$$

This formula is very nearly exact for all arcs less than one-quarter of the periphery. The error is only about one per cent for a quarter circle, and decreases for smaller arcs.





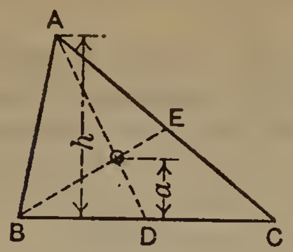
Area of Trapezoid. — The center of gravity is on the line joining the middle points of parallel lines AB and DE.

$$c = \frac{h\,(a + 2\,b)}{3\,(a + b)} \qquad d = \frac{h\,(2\,a + b)}{3\,(a + b)}$$

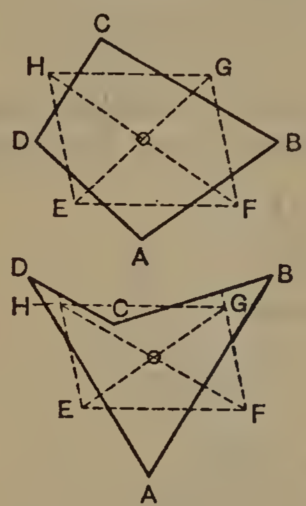
$$e = \frac{a^2 + ab + b^2}{3\,(a + b)}$$

The trapezoid can also be divided into two triangles. The center of gravity is at the intersection of the line joining the centers of gravity of the triangles, and the middle line FG.

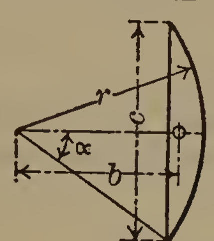
Center of Gravity



Area of Triangle. — The center of gravity is at the intersection of lines AD and BE, which bisect the sides BC and AC. The perpendicular distance from the center of gravity to any one of the sides is equal to one-third the height perpendicular to that side. Hence, $a = h \div 3$.



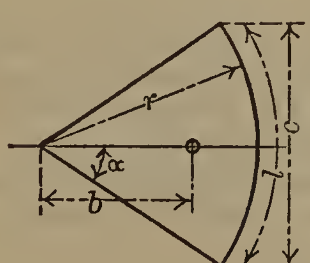
Any Four-sided Figure. — Two cases are possible, as shown in the illustration. To find the center of gravity of the four-sided figure $ABCD$, each of the sides is divided into three equal parts. A line is then drawn through each pair of division points next to the points of intersection A, B, C, and D of the sides of the figure. These lines form a parallelogram $EFGH$; the intersection of the diagonals EG and FH locates the required center of gravity.



Circle Segment. — The distance of the center of gravity from the center of the circle is:

$$b = \frac{c^3}{12\,A} = \frac{2}{3} \times \frac{r^3 \sin^3 \alpha}{A}$$

in which A = area of segment.



Circle Sector. — Distance b from center of gravity to center of circle is:

$$b = \frac{2\,rc}{3\,l} = \frac{r^2c}{3\,A} = 38.197\,\frac{r \sin \alpha}{\alpha}$$

in which A = area of sector, and α is expressed in degrees.

For the area of a half-circle:

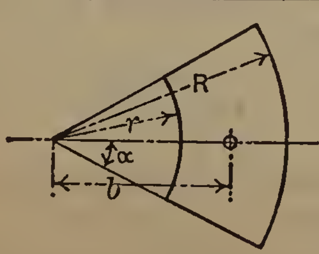
$$b = 4\,r \div 3\,\pi = 0.4244\,r$$

For the area of a quarter circle:

$$b = 4\,\sqrt{2} \times r \div 3\,\pi = 0.6002\,r$$

For the area of a sixth of a circle:

$$b = 2\,r \div \pi = 0.6366\,r$$

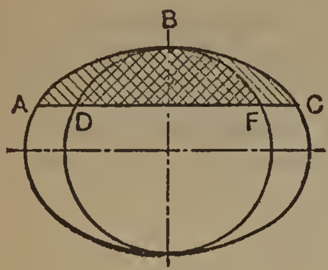


Part of Circle Ring. — Distance b from center of gravity to center of circle is:

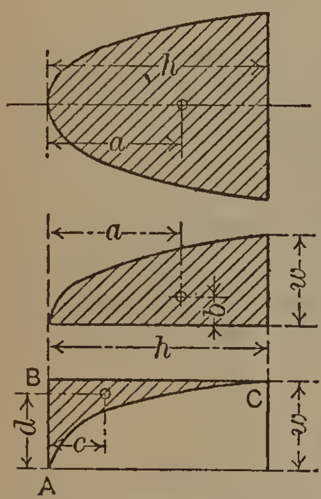
$$b = 38.197\,\frac{(R^3 - r^3) \sin \alpha}{(R^2 - r^2)\,\alpha}$$

Angle α is expressed in degrees.

Center of Gravity



Segment of an Ellipse. — The center of gravity of an elliptic segment ABC, symmetrical about one of the axes, coincides with the center of gravity of the segment DBF of a circle, the diameter of which is equal to that axis of the ellipse about which the elliptic segment is symmetrical.



Area of a Parabola. — For the complete parabolic area, the center of gravity is on the center line or axis, and

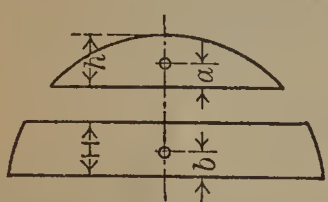
$$a = \frac{3h}{5}$$

For one-half of the parabola:

$$a = \frac{3h}{5} \quad \text{and} \quad b = \frac{3w}{8}$$

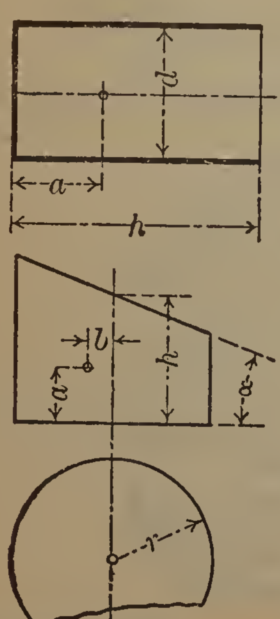
For the complement area ABC:

$$c = 0.3h \quad \text{and} \quad d = 0.75w$$



Spherical Surface of Segments and Zones of Spheres. — Distances a and b which determine the center of gravity, are:

$$a = \frac{h}{2} \qquad b = \frac{H}{2}$$



Cylinder. — The center of gravity of a solid cylinder (or prism) with parallel end surfaces, is located at the middle of the line that joins the centers of gravity of the end surfaces.

The center of gravity of a cylindrical surface or shell, with the base or end surface in one end, is found from:

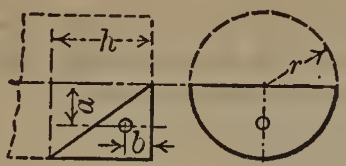
$$a = \frac{2h^2}{4h + d}$$

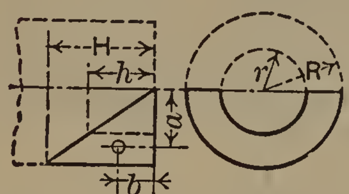
The center of gravity of a cylinder cut off by an inclined plane is located by:

$$a = \frac{h}{2} + \frac{r^2 \tan^2 \alpha}{8h} \qquad b = \frac{r^2 \tan \alpha}{4h}$$

where α is the angle between the obliquely cut off surface and the base surface.

Center of Gravity





Portion of Cylinder. — For a solid portion of a cylinder, as shown, the center of gravity is determined by:

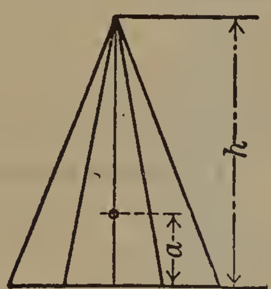
$$a = \tfrac{3}{16} \times 3.1416\, r \qquad b = \tfrac{3}{32} \times 3.1416\, h$$

For the cylindrical surface only:

$$a = \tfrac{1}{4} \times 3.1416\, r \qquad b = \tfrac{1}{8} \times 3.1416\, h$$

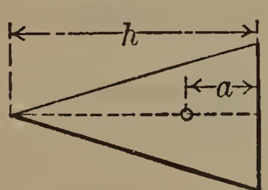
If the cylinder is hollow, the center of gravity of the solid shell is found by:

$$a = \tfrac{3}{16} \times 3.1416\, \frac{R^4 - r^4}{R^3 - r^3}; \quad b = \tfrac{3}{32} \times 3.1416\, \frac{H^4 - h^4}{H^3 - h^3}$$



Pyramid. — In a solid pyramid the center of gravity is located on the line joining the apex with the center of gravity of the base surface, at a distance from the base equal to one-quarter of the height; or $a = \frac{1}{4} h$.

The center of gravity of the triangular surfaces forming the pyramid is located on the line joining the apex with the center of gravity of the base surface, at a distance from the base equal to one-third of the height; or $a = \frac{1}{3} h$.

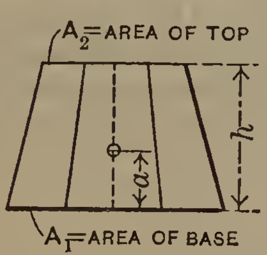


Cone. — The same rules apply as for the pyramid. For the solid cone:

$$a = \tfrac{1}{4} h$$

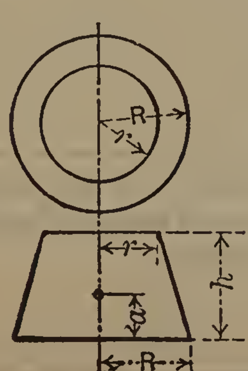
For the conical surface:

$$a = \tfrac{1}{3} h$$



Frustum of Pyramid. — The center of gravity is located on the line that joins the centers of gravity of the end surfaces. If A_1 = area of base surface, and A_2 area of top surface,

$$a = \frac{h\,(A_1 + 2\sqrt{A_1 \times A_2} + 3\,A_2)}{4\,(A_1 + \sqrt{A_1 \times A_2} + A_2)}.$$



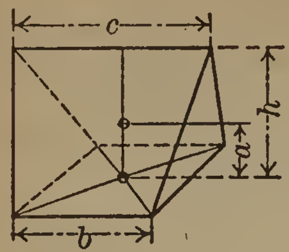
Frustum of Cone. — The same rules apply as for the frustum of a pyramid. For a solid frustum of a circular cone the formula below is also used:

$$a = \frac{h\,(R^2 + 2\,Rr + 3\,r^2)}{4\,(R^2 + Rr + r^2)}$$

The location of the center of gravity of the conical surface of a frustum of a cone is determined by:

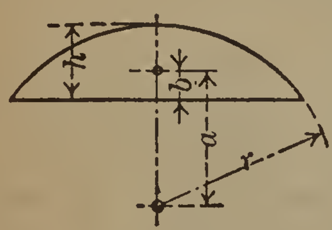
$$a = \frac{h\,(R + 2\,r)}{3\,(R + r)}$$

Center of Gravity



Wedge. — The center of gravity is on the line joining the center of gravity of the base with the middle point of the edge, and is located at:

$$a = \frac{h\,(b + c)}{2\,(2\,b + c)}$$

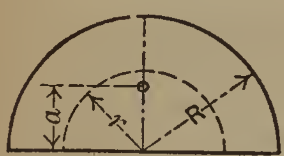


Spherical Segment. — The center of gravity of a solid segment is determined by:

$$a = \frac{3\,(2\,r - h)^2}{4\,(3\,r - h)}$$

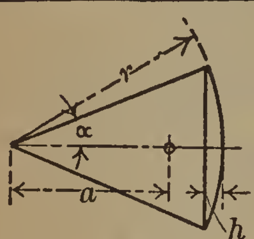
$$b = \frac{h\,(4\,r - h)}{4\,(3\,r - h)}$$

For a half-sphere, $a = b = \frac{3}{8}\,r$



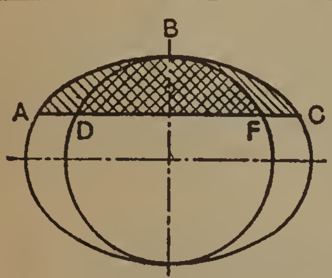
Half of a Hollow Sphere. — The center of gravity is located at:

$$a = \frac{3\,(R^4 - r^4)}{8\,(R^3 - r^3)}$$

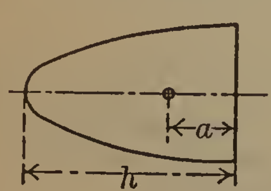


Spherical Sector. — The center of gravity of a solid sector is at:

$$a = \tfrac{3}{8}\,(1 + \cos\alpha)\,r = \tfrac{3}{8}\,(2\,r - h)$$

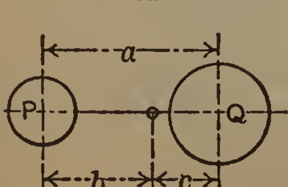


Segment of Ellipsoid or Spheroid. — The center of gravity of a solid segment ABC, symmetrical about the axis of rotation, coincides with the center of gravity of the segment DBF of a sphere, the diameter of which is equal to the axis of rotation of the spheroid.



Paraboloid. — The center of gravity of a solid paraboloid of rotation is at:

$$a = \tfrac{1}{3}\,h$$



Center of Gravity of Two Bodies. — If the weights of the bodies are P and Q, and the distance between their centers of gravity is a, then:

$$b = \frac{Qa}{P + Q} \qquad c = \frac{Pa}{P + Q}$$

Center of Gravity of Figures of any Outline. — If the figure is symmetrical about a center line, as in Fig. 1, the center of gravity will be located on that line. To find the exact location on that line, the simplest method is by taking moments with reference to any convenient axis at right angles to this center line. Divide the area into geometrical figures, the centers of gravity of which can be easily found. In this case, divide the figure into three rectangles *KLMN*, *EFGH* and *OPRS*. Call the areas of these rectangles *A*, *B* and *C*, respectively, and find the center of gravity of each. Then select any convenient axis, as *XX*, at right angles to the center line *YY*, and determine distances *a*, *b* and *c*. The distance *y* of the center of gravity of the complete figure from the axis *XX* is then found from the equation:

$$y = \frac{Aa + Bb + Cc}{A + B + C}$$

As an example, assume that the area *A* is 24 square inches, *B*, 14 square inches,

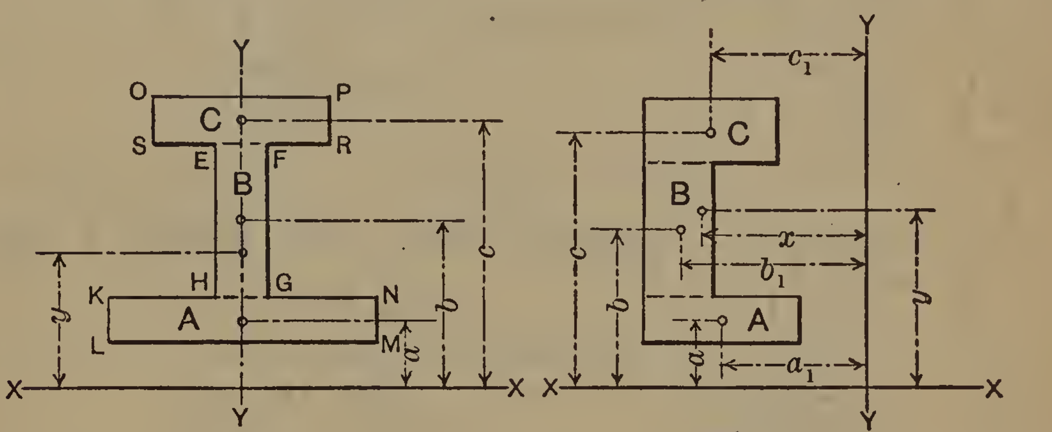


Fig. 1 Fig. 2

and *C*, 16 square inches, and that $a = 3$ inches, $b = 7.5$ inches, and $c = 12$ inches. Then:

$$y = \frac{24 \times 3 + 14 \times 7.5 + 16 \times 12}{24 + 14 + 16} = \frac{369}{54} = 6.83 \text{ inches.}$$

If the figure, the center of gravity of which is to be found, is not symmetrical about any axis, then moments must be taken with relation to two axes *XX* and *YY*, as shown in Fig. 2. The figure is divided into convenient geometrical figures, the centers of gravity of which can be easily found, the same as before. The center of gravity is determined by the equations:

$$x = \frac{Aa_1 + Bb_1 + Cc_1}{A + B + C} \qquad y = \frac{Aa + Bb + Cc}{A + B + C}$$

As an example, let $A = 14$ square inches, $B = 18$ square inches, and $C = 20$ square inches. Let $a = 3$ inches, $b = 7$ inches, and $c = 11.5$ inches. Let $a_1 = 6.5$ inches, $b_1 = 8.5$ inches, and $c_1 = 7$ inches. Then:

$$x = \frac{14 \times 6.5 + 18 \times 8.5 + 20 \times 7}{14 + 18 + 20} = \frac{384}{52} = 7.38 \text{ inches.}$$

$$y = \frac{14 \times 3 + 18 \times 7 + 20 \times 11.5}{14 + 18 + 20} = \frac{398}{52} = 7.65 \text{ inches.}$$

In other words, the center of gravity is located at a distance of 7.65 inches from the axis *XX* and 7.38 inches from the axis *YY*.

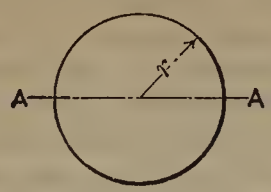
Moments of Inertia

(W = weight of body)

	*Prism.* — With reference to axis $A - A$: $I = \frac{W}{12}(h^2 + b^2)$ With reference to axis $B - B$: $I = W\left(\frac{l^2}{3} + \frac{h^2}{12}\right)$
	*Cylinder.* — With reference to axis $A - A$: $I = \frac{1}{2} Wr^2$ With reference to axis $B - B$: $I = W\left(\frac{l^2}{3} + \frac{r^2}{4}\right)$
	*Hollow Cylinder.* — With reference to axis $A - A$: $I = \frac{1}{2} W(R^2 + r^2)$ With reference to axis $B - B$: $I = W\left(\frac{l^2}{3} + \frac{R^2 + r^2}{4}\right)$
	*Pyramid,* rectangular base. — With reference to axis $A - A$: $I = \frac{W}{20}(a^2 + b^2)$ With reference to axis $B - B$ (through the center of gravity): $I = W\left(\frac{3}{80}h^2 + \frac{b^2}{20}\right)$
	*Cone.* — With reference to axis $A - A$: $I = \frac{3W}{10}r^2$ With reference to axis $B - B$ (through the center of gravity): $I = \frac{3W}{20}\left(r^2 + \frac{h^2}{4}\right)$
	*Frustum of Cone.* — With reference to axis $A - A$: $I = \frac{3W(R^5 - r^5)}{10(R^3 - r^3)}$

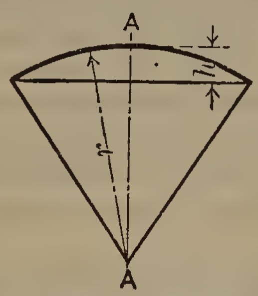
Moments of Inertia

(W = weight of body)



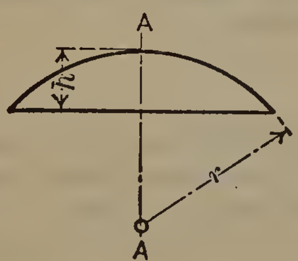
Sphere. — With reference to any axis through the center:

$$I = \tfrac{2}{5} Wr^2$$



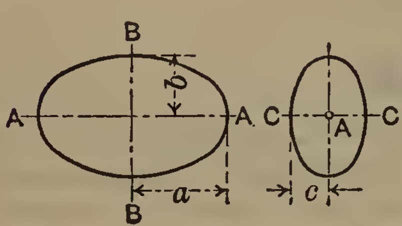
Spherical Sector. — With reference to axis $A-A$:

$$I = \frac{W}{5}(3\,rh - h^2)$$



Spherical Segment. — With reference to axis $A-A$:

$$I = W\left(r^2 - \frac{3\,rh}{4} + \frac{3\,h^2}{20}\right)\frac{2\,h}{3\,r-h}$$



Ellipsoid. — With reference to axis $A-A$:

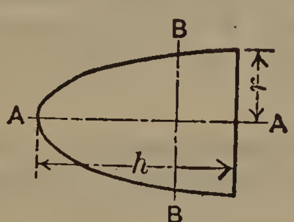
$$I = \frac{W}{5}(b^2 + c^2)$$

With reference to axis $B-B$:

$$I = \frac{W}{5}(a^2 + c^2)$$

With reference to axis $C-C$:

$$I = \frac{W}{5}(a^2 + b^2)$$

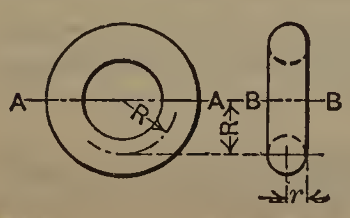


Paraboloid. — With reference to axis $A-A$:

$$I = \tfrac{1}{3} Wr^2$$

With reference to axis $B-B$ (through the center of gravity):

$$I = W\left(\frac{r^2}{6} + \frac{h^2}{18}\right)$$



Torus. — With reference to axis $A-A$:

$$I = W\left(\frac{R^2}{2} + \frac{5\,r^2}{8}\right)$$

With reference to axis $B-B$:

$$I = W\left(R^2 + \tfrac{3}{4} r^2\right)$$

Moment of Inertia. — The moment of inertia of a body, with respect to an axis, is the sum of the products obtained by multiplying the weights of each elementary particle by the square of its distance from the axis. Hence, the moment of inertia of the same body varies according to the position of the axis. It has its minimum value when the axis passes through the center of gravity. The moment of inertia is numerically equal to the weight of a body which, if it could be conceived of as concentrated at a distance of unity from the axis of rotation, would, if actuated by the same forces, rotate with the same angular velocity as that of the actual body. In other words, the moment of inertia bears the same relation to angular acceleration as weight does to linear acceleration. When the term moment of inertia is used in regard to areas, it is equal to the sum of the products obtained by multiplying each elementary area by the square of its distance from the axis. The moments of inertia of a number of solids are given on the two preceding pages. The moments of inertia of surfaces are especially useful in calculating the strength of beams, and the moments for a number of different cross-sections are given later in connection with the beam formulas.

If the moment of inertia I of a solid or surface, with respect to an axis through its center of gravity, is known, then the moment of inertia with respect to any parallel axis at a distance a from the axis through the center of gravity, is:

$$I_a = I + A \times a^2$$

in which A = the weight or area of the solid or figure of which the moment of inertia is to be found. For example, assume that the moment of inertia of a body weighing 3 pounds is 18 with reference to an axis through the center of gravity. Find the moment of inertia with reference to a parallel axis at a distance of 5 inches from the axis through the center of gravity.

$$I_a = 18 + 3 \times 5^2 = 18 + 75 = 93.$$

Motion, Force and Work

Motion is a progressive change of position of a body. Velocity is the rate of motion. When the velocity of a body is the same at every moment during which the motion takes place, the latter is called *uniform*. When the velocity is variable and constantly increasing, the rate at which it changes is called *acceleration;* that is, acceleration is the rate at which the velocity of a body changes in a unit of time, as the change in feet per second, in one second. When the motion is decreasing instead of increasing, it is called *retarded* motion, and the rate at which the motion is retarded is frequently called the *de-acceleration.* If the acceleration is uniform, the motion is called *uniformly accelerated* motion. An example of such motion is found in that of falling bodies.

Newton's Laws of Motion. — *First Law.* Every body continues in a state of rest or in uniform motion in a straight line, except if it is compelled by a force to change its state of rest or motion.

Second Law. If a body is acted upon by several forces, it is acted upon by each of these as if the others did not exist. This is true whether the body is at rest or in motion. In other words, if two or more forces act upon a body at the same time, each produces exactly the same effect as if it acted alone; the total effect or resultant motion of *all* the forces may be found by a diagram in the same way as the resultant of forces is found.

Third Law. To every action there is always an equal reaction, or, in other words, if a force acts to change the state of motion of a body, the body offers a resistance equal and directly opposite to the force.

Mass. — The *mass* of a body equals the weight divided by the acceleration due to gravity, or:

$$\text{Mass} = \frac{\text{weight}}{32.16}$$

General Formulas for Motion. — In the following formulas:

F = force in pounds;
S = space in feet;
T = time in seconds;
V = velocity in feet per second;
P = power in foot-pounds per second;
K = work in foot-pounds;
H.P. = horsepower.

The relations between these various quantities are given in the following formulas:

$$F = \frac{P}{V} = \frac{K}{S} = \frac{K}{VT} = \frac{550\,\text{H.P.}}{V}$$

$$S = VT = \frac{PT}{F} = \frac{K}{F} = \frac{550\,T\,\text{H.P.}}{F}$$

$$T = \frac{S}{V} = \frac{FS}{P} = \frac{K}{FV} = \frac{FS}{550\,\text{H.P.}}$$

$$V = \frac{S}{T} = \frac{P}{F} = \frac{K}{FT} = \frac{550\,\text{H.P.}}{F}$$

$$P = FV = \frac{FS}{T} = \frac{K}{T} = 550\,\text{H.P.}$$

$$K = FS = PT = FVT = 550\,T\,\text{H.P.}$$

$$\text{H.P.} = \frac{P}{550} = \frac{FV}{550} = \frac{FS}{550\,T} = \frac{K}{550\,T}$$

Example: — A casting weighing 300 pounds is to be lifted by means of an overhead crane. The casting is lifted 10 feet in 12 seconds. What is the horsepower developed? Here $F = 300$; $S = 10$; $T = 12$.

$$\text{H.P.} = \frac{F \times S}{550\,T} = \frac{300 \times 10}{550 \times 12} = 0.45.$$

Momentum. — The momentum of a moving body is equivalent to that constant force which would bring the body to rest in one second by resisting its movement.

$$\text{Momentum} = \text{mass} \times \text{velocity in feet per second}$$

$$= \frac{\text{weight}}{32.16} \times \text{velocity in feet per second.}$$

(Momentum should not be confused with the moment of a force, which is equal to the force multiplied by its lever arm.)

Falling Bodies

Under the influence of gravity alone, all bodies fall to the earth with the same velocity and with the same acceleration. The value of the acceleration is commonly denoted by the letter g. The acceleration increases with the latitude and decreases with the elevation above the level of the sea. Its value at the level of the sea in the latitude of New York is 32.16 feet per second. (In the metric system g equals 9.81 meters per second at 45 degrees latitude and sea level.)

Formulas for Accelerated Motion. — In the following formulas:

V = velocity in feet per second of a falling body at the end of time T;
T = time in seconds the body is falling;
S = space in feet which the falling body passes through in time T;
u = space in feet which the body falls in the Tth second;
g = acceleration due to gravity.

$$V = gT = \frac{2S}{T} = \sqrt{2gS} = 8.02\sqrt{S}$$

$$S = \frac{1}{2}gT^2 = \frac{1}{2}VT = \frac{V^2}{2g} = \frac{V^2}{64.32}$$

$$T = \frac{V}{g} = \frac{2S}{V} = \sqrt{\frac{2S}{g}} = \frac{\sqrt{S}}{4.01} = \frac{u}{g} + \frac{1}{2}$$

$$u = g(T - \tfrac{1}{2})$$

Examples: What velocity has a body attained after having fallen for a time of 5 seconds?

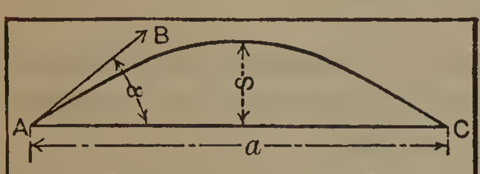
$$V = gT = 32.16 \times 5 = 160.8 \text{ feet per second.}$$

A metal ball falls from the top of a tower 300 feet high. What length of time will be required before it reaches the ground?

$$T = \sqrt{\frac{2S}{g}} = \sqrt{\frac{2 \times 300}{32.16}} = \sqrt{18.66} = 4.32 \text{ seconds.}$$

What is the velocity of the ball in the previous example when it reaches the ground?

$$V = \sqrt{2gS} = \sqrt{2 \times 32.16 \times 300} = \sqrt{19{,}296} = 139 \text{ feet, nearly.}$$



Bodies thrown at an Angle with the Vertical. — When a body is thrown in a direction other than vertical, it describes a parabolic curve. If V (represented by line AB) is the velocity at which the body is thrown from a given point, T the time it requires to pass from A to C, and the other quantities are as noted in the accompanying engraving, then:

$$a = \frac{2V^2 \sin\alpha \cos\alpha}{g}; \qquad T = \frac{2V \sin\alpha}{g}; \qquad S = \frac{V^2 \sin^2\alpha}{2g}.$$

Example: A bullet is fired in the air at an angle of 45 degrees. The initial velocity is 600 feet per second. How far will it pass before striking the ground?

$$a = \frac{2 \times 600^2 \times 0.707 \times 0.707}{g} = 11{,}200 \text{ feet, approx.}$$

The distance a projectile will travel is greatest when its initial direction is at an angle of 45 degrees with the horizontal.

Retarded Motion. — When a body is thrown vertically upwards, its motion will be retarded in the same ratio as it is accelerated when falling, the retardation or de-acceleration being 32.16 feet per second. In the following formulas: V = velocity at which the body begins to ascend; T = time in seconds passing before the body reaches the highest point, or the point of return; t = any time less than T; S = height in feet to which the body will ascend before reaching its greatest height; s = space body ascends in time t; v = velocity at the end of time t.

$$V = v + gt = \frac{s}{t} + \frac{gt}{2} = \sqrt{v^2 + 2\,gs}$$

$$v = V - gt = \frac{s}{t} - \frac{gt}{2} = \sqrt{V^2 - 2\,gs}$$

$$s = t\left(V - \frac{gt}{2}\right) = t\left(v + \frac{gt}{2}\right)$$

$$t = \frac{V - v}{g} = \frac{V}{g} - \sqrt{\frac{V^2}{g^2} - \frac{2\,s}{g}}$$

The formulas for T and S are the same as for accelerated motion.

Examples: With what velocity should a ball start to ascend in order to strike an object 30 feet above with a velocity of 20 feet per second?

$$V = \sqrt{v^2 + 2\,gs} = \sqrt{20^2 + 2 \times 32.16 \times 30} = 48.27 \text{ feet.}$$

An object is thrown vertically into the air with a velocity of 100 feet per second. When does it reach the highest point and start to return?

$$T = \frac{V}{g} = \frac{100}{32.16} = 3.11 \text{ seconds.}$$

Energy. — A body is said to possess energy when it is capable of doing work or of overcoming resistance. The energy may be either *kinetic* or *potential*. Thus, energy possessed by a body on account of its motion is kinetic or actual energy, and it is expressed in foot-pounds. Potential or latent energy is the capacity for doing work possessed by a body on account of its position or chemical composition. For example, a weight that has been lifted to some point possesses potential energy, and when the weight falls, this potential energy is changed to kinetic energy. Water stored in a reservoir and the heat or chemical energy in fuel and gunpowder are other examples of potential energy. If E = energy in foot-pounds; M = mass (weight ÷ 32.16); V = velocity in feet per second; S = total space passed through in feet; and W = weight in pounds; then:

$$E = \frac{1}{2} MV^2 = \frac{WV^2}{2\,g} = \frac{WV^2}{64.32}$$

For a falling body, acted upon by gravity alone, $E = SW$.

As an example of the use of the formulas involving velocities of falling bodies and energy, the following example is given: A projectile is fired from a 12-inch gun vertically into the air. It strikes the ground, coming down, exactly 1 minute and 40 seconds after leaving the muzzle. Disregarding air resistance, what height did the projectile reach? What was its velocity when leaving the muzzle? And what is the energy of the projectile when it strikes the ground, if its weight is assumed to be 600 pounds?

The time required for the projectile to reach its greatest height is one-half of the total time for the upward and downward journey. Thus, in 50 seconds, the projectile has reached the point where its velocity is zero, and where it begins to fall.

Hence, using the formulas given for falling bodies:

$$S = \frac{32.16 \times 50^2}{2} = \frac{32.16 \times 2500}{2} = 40,200 \text{ feet,}$$

or

$$\frac{40,200}{5,280} = 7.6 \text{ miles, approximately.}$$

The velocity of the projectile when leaving the muzzle is the same as the velocity acquired when again reaching the ground. This velocity is found by the formula:

$$V = gT = 32.16 \times 50 = 1608 \text{ feet per second.}$$

The energy of the projectile when it strikes the ground equals its weight multiplied by the distance through which it has fallen. If W = weight, and E = energy, we have:

$$E = W \times S = 600 \times 40,200 = 24,120,000 \text{ foot-pounds;}$$

or by another formula for the energy:

$$E = \frac{WV^2}{2g} = \frac{600 \times 1608^2}{2 \times 32.16} = \frac{600 \times 2,585,664}{2 \times 32.16} = 24,120,000 \text{ foot-pounds.}$$

Motion on Inclined Planes. — When a body descends an inclined plane, actuated by the force of gravity, its velocity, friction being neglected, is equal to that acquired by a body falling freely the height of the plane. The formulas for uniformly accelerated motion apply to motion on inclined planes.

V = velocity of body sliding down an inclined plane, in feet per second, at end of time T;
S = space traversed in feet;
T = time in seconds;
α = the angle of the plane with the horizontal;
g = acceleration due to gravity = 32.16.

$$V = gT \sin\alpha = \sqrt{2\,gS \sin\alpha}$$

$$S = \frac{gT^2 \sin\alpha}{2} = \frac{V^2}{2\,g \sin\alpha}$$

$$T = \frac{V}{g \sin\alpha} = \sqrt{\frac{2\,S}{g \sin\alpha}}$$

Force of a Blow. — The energy of a body raised to a given height and permitted to fall, as in the case of a drop hammer, is equal to the weight multiplied by the height through which it falls. Hence, the force of a blow cannot be expressed directly in pounds, but the energy with which a hammer will strike a piece of work can be expressed in foot-pounds. The average force of the blow, then, is equal to the number of foot-pounds, divided by the amount of the penetration. When the force of a blow is calculated, the weight of the falling body should always be added to the energy due to the fall. If W = weight of falling body in pounds; S = the height through which it has fallen in feet; and d = distance in feet the object struck is moved (or penetrated), then:

$$\text{average force of blow} = \frac{WS}{d} + W.$$

Example 1: — A pile driver weighing 200 pounds strikes the top of the pile after having fallen from a height of 20 feet. It forces the pile into the ground a distance of 6 inches. Before the ram is brought to rest, it will then have performed $200 \times 20 = 4000$ foot-pounds of work, and as this energy is expended in a distance of one-half foot, the average force of the blow equals $4000 \div \frac{1}{2} + 200 = 8200$ pounds.

Example 2: — If, upon reaching the ground, the projectile in the example given on page 277, buries itself to a depth of 8 feet, what is the average force of the blow with which it strikes the ground?

$$F = \frac{E}{d} + W = \frac{24,120,000}{8} + 600 = 3,015,600 \text{ pounds.}$$

Center and Radius of Oscillation. — If a body oscillates about a horizontal axis which does not pass through its center of gravity, there will be a point on the line drawn from the center of gravity, perpendicular to the axis, the motion of which will be the same as if the whole mass were concentrated at that point. This point is called the *center of oscillation*. The *radius of oscillation* is the distance between the center of oscillation and the point of suspension. In a straight line, or in a bar of small diameter, suspended at one end and oscillating about it, the center of oscillation is at two-thirds the length of the rod from the end by which it is suspended.

When the vibrations are perpendicular to the plane of the figure, and the figure is suspended by the vertex of an angle or its uppermost point, the radius of oscillation of an isosceles triangle is equal to ¾ of the height of the triangle; of a circle, ⅝ of the diameter; of a parabola, 5/7 of the height.

If the vibrations are in the plane of the figure, then the radius of oscillation of a circle equals ¾ of the diameter; of a rectangle, suspended at the vertex of one angle, ⅔ of the diagonal.

Center of Percussion. — If a body oscillates about an axis, then the point at which, if a blow is struck by the body, the percussive action is the same as if the whole mass of the body were concentrated at that point, is called the *center of percussion.* This point is located at the same point as the center of oscillation.

Center and Radius of Gyration. — The center of gyration with reference to an axis is the point at which the entire weight of a body may be considered as concentrated, the moment of inertia, meanwhile, remaining unchanged; or, in a revolving body, the center of gyration is the point at which the whole weight of the body may be considered as concentrated, the angular velocity remaining the same. The *radius of gyration* is the distance from this point to the axis of rotation. If W is the weight of a body; I, its moment of inertia; and k, the radius of gyration, then:

$$k = \sqrt{\frac{I}{W}} \quad \text{and} \quad I = Wk^2.$$

To find the radius of gyration of an area, as the cross-section of a beam, divide the moment of inertia of the area by the area and extract the square root.

The square of the radius of gyration of an oscillating body is equal to the product of the radius of oscillation multiplied by the distance of the center of gravity of the suspended body from the point of suspension.

When the axis, with reference to which the radius of gyration is taken, passes through the center of gravity, the radius of gyration is the least possible and is called the *principal* radius of gyration.

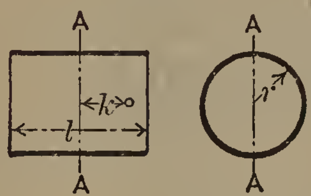
For a solid cylindrical body, like a disk or emery wheel, the radius of gyration is equal to the radius of the disk divided by $\sqrt{2}$ (= radius $\times$ 0.707). For a flywheel rim, it is sufficiently accurate to assume the radius of gyration to be the distance from the center to a point halfway between the outer and inner edges of the rim.

Radius of Gyration

Bar of Small Diameter. Axis at end.  $k = 0.5773\,l$ $k^2 = \frac{1}{3}\,l^2$ Axis at center.  $k = 0.2886\,l$ $k^2 = \frac{1}{12}\,l^2$	Thin Circular Disk. Axis through center. Cylinder. Axis through center.  $k = 0.7071\,r$ $k^2 = \frac{1}{2}\,r^2$	Cylinder. Axis, diameter at mid-length.  $k = 0.289\sqrt{l^2 + 3\,r^2}$ $k^2 = \frac{l^2}{12} + \frac{r^2}{4}$
Bar of Small Diameter, bent to Circular Shape. Axis, a diameter of the ring.  $k = 0.7071\,r$ $k^2 = \frac{1}{2}\,r^2$	Thin Circular Disk. Axis its diameter.  $k = \frac{1}{2}\,r$ $k^2 = \frac{1}{4}\,r^2$	Cylinder. Axis, diameter at end.  $k = 0.289\sqrt{4\,l^2 + 3\,r^2}$ $k^2 = \frac{l^2}{3} + \frac{r^2}{4}$
Bar of Small Diameter, bent to Circular Shape. Axis through center of ring.  $k = r$; $k^2 = r^2$	Parallelogram (Thin flat plate). Axis at base.  $k = 0.5773\,h$; $k^2 = \frac{1}{3}\,h^2$ Axis at mid-height.  $k = 0.2886\,h$; $k^2 = \frac{1}{12}\,h^2$	Thin, Flat, Circular Ring. Axis its diameter.  $k = \frac{1}{4}\sqrt{D^2 + d^2}$ $k^2 = \frac{D^2 + d^2}{16}$

Radius of Gyration

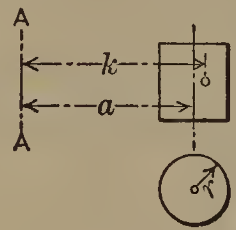
Thin Hollow Cylinder.
Axis, diameter at mid-length.



$$k = 0.289\sqrt{l^2 + 6r^2}$$

$$k^2 = \frac{l^2}{12} + \frac{r^2}{2}$$

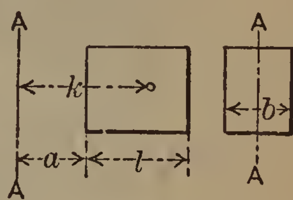
Cylinder.
Axis at a distance.



$$k = \sqrt{a^2 + \tfrac{1}{2}r^2}$$

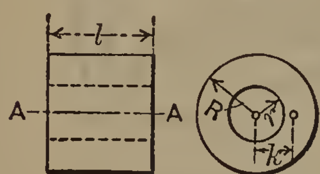
$$k^2 = a^2 + \tfrac{1}{2}r^2$$

Parallelepiped.
Axis at distance from end.



$$k = \sqrt{\frac{4l^2 + b^2}{12} + a^2 + al}$$

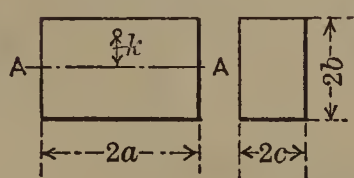
Hollow Cylinder.
Longitudinal Axis.



$$k = 0.7071\sqrt{R^2 + r^2}$$

$$k^2 = \tfrac{1}{2}(R^2 + r^2)$$

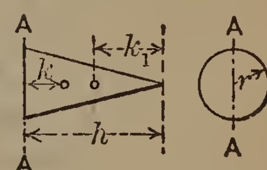
Rectangular Prism.
Axis through center.



$$k = 0.577\sqrt{b^2 + c^2}$$

$$k^2 = \tfrac{1}{3}(b^2 + c^2)$$

Cone.
Axis at base.

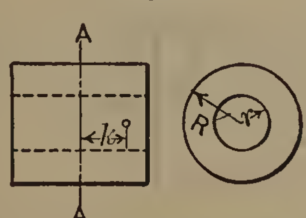


$$k = \sqrt{\frac{2h^2 + 3r^2}{20}}$$

Axis at apex.

$$k_1 = \sqrt{\frac{12h^2 + 3r^2}{20}}$$

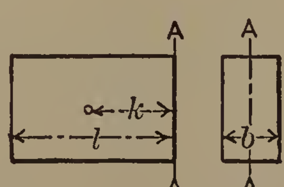
Hollow Cylinder.
Axis, diameter at mid-length.



$$k = 0.289\sqrt{l^2 + 3(R^2 + r^2)}$$

$$k^2 = \frac{l^2}{12} + \frac{R^2 + r^2}{4}$$

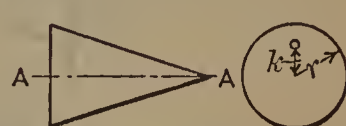
Parallelepiped.
Axis at one end, central.



$$k = 0.289\sqrt{4l^2 + b^2}$$

$$k^2 = \frac{4l^2 + b^2}{12}$$

Cone.
Axis through its center line.

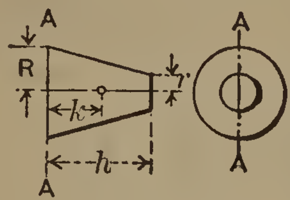


$$k = 0.5477\,r$$

$$k^2 = 0.3\,r^2$$

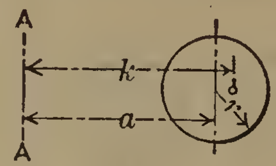
Radius of Gyration

Frustum of Cone.
Axis at large end.



$$k=\sqrt{\frac{h}{10}\left(\frac{R^2+3\,Rr+r^2}{R^2+Rr+r^2}\right)+\frac{3}{20}\left(\frac{R^5-r^5}{R^3-r^3}\right)}$$

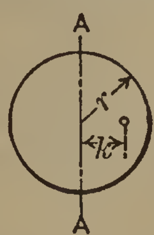
Sphere.
Axis at a distance.



$k=\sqrt{a^2+\frac{2}{5}r^2}$

$k^2=a^2+\frac{2}{5}r^2$

Sphere.
Axis its diameter.

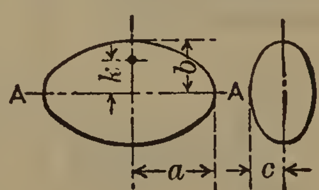


$k=0.6325\,r;\quad k^2=\frac{2}{5}r^2$

Thin Spherical Shell.

$k=0.8165\,r;\quad k^2=\frac{2}{3}r^2$

Ellipsoid.
Axis through center.



$k=0.447\sqrt{b^2+c^2}$

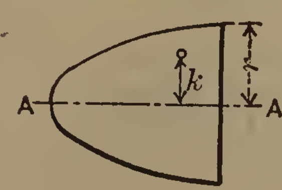
$k^2=\frac{1}{5}(b^2+c^2)$

Hollow Sphere.
Axis its diameter.

$$k=0.6325\sqrt{\frac{R^5-r^5}{R^3-r^3}}$$

$$k^2=\frac{2\,(R^5-r^5)}{5\,(R^3-r^3)}$$

Paraboloid.
Axis through center.



$k=0.5773\,r$

$k^2=\frac{1}{3}r^2$

Formulas for Rotary Motion

In the following formulas:

F = force in pounds, acting in the direction of the tangent;
P = power in foot-pounds, per second;
V = velocity in feet per second;
S = distance passed through in feet by point of application of force F;
T = time in seconds;
K = work in foot-pounds;
R = radius of revolution (radius to point of application of force F) in feet;
n = revolutions per minute;
N = total number of revolutions in time T;
H.P. = horsepower.

$$F = \frac{60\,P}{2\,\pi Rn} = \frac{9.55\,P}{Rn} = \frac{9.55\,K}{RnT} = \frac{5252\text{ H.P.}}{Rn}$$

$$P = \frac{2\,\pi RnF}{60} = \frac{RnF}{9.55} = \frac{FRN}{0.159\,T}$$

$$V = \frac{2\,\pi Rn}{60} = 0.1047\,Rn$$

$$S = \frac{2\,\pi RnT}{60} = \frac{RnT}{9.55} = 2\,\pi RN$$

$$T = \frac{60\,S}{2\,\pi Rn} = \frac{9.55\,S}{Rn} = \frac{9.55\,K}{FRn} = \frac{FRN}{87.5\text{ H.P.}}$$

$$K = \frac{2\,\pi FRnT}{60} = \frac{FRnT}{9.55} = 2\,\pi RNF$$

$$R = \frac{60\,V}{2\,\pi n} = \frac{9.55\,V}{n} = \frac{9.55\,P}{Fn} = \frac{5252\text{ H.P.}}{Fn} = \frac{9.55\,K}{FnT}$$

$$n = \frac{60\,V}{2\,\pi R} = \frac{9.55\,V}{R} = \frac{5252\text{ H.P.}}{FR}$$

$$N = \frac{87.5\,T\text{ H.P.}}{FR} = \frac{S}{2\,\pi R} = \frac{K}{2\,\pi RF} = \frac{9.55\,PT}{FR}$$

$$\text{H.P.} = \frac{FRn}{5252} = \frac{FRN}{87.5\,T}$$

Examples: — A pulley, 36 inches (3 feet) in diameter, makes 110 revolutions per minute. The pull of the belt on the pulley is 200 pounds. Find the horsepower transmitted. Here $F = 200$; $R = 1.5$; $n = 110$.

$$\text{H.P.} = \frac{FRn}{5252} = \frac{200 \times 1.5 \times 110}{5252} = 6.3.$$

What is the force exerted at the periphery of a gear 18 inches in diameter, revolving at 60 revolutions per minute and transmitting 4 horsepower? Here $R = 0.75$; $n = 60$.

$$F = \frac{5252 \times \text{H.P.}}{Rn} = \frac{5252 \times 4}{0.75 \times 60} = 467\text{ pounds.}$$

General Formulas for Accelerated or Retarded Motion

In the following formulas:

F = force in pounds causing acceleration, acting on a body free to move;
T = time in seconds during which the force acts on the body;
G = constant acceleration in feet per second, due to the force F;
V = final velocity at the end of time T, or uniform velocity of a moving body;
S = distance in feet passed through while the force acts on the body;
W = force required to move body at uniform velocity, in pounds;
P = average power exerted during time T, in foot-pounds per second;
K = work in foot-pounds (or energy) concentrated in the moving body;
g = acceleration due to gravity = 32.16.

$$F = \frac{GW}{g} = \frac{VW}{gT} = \frac{2\,WS}{gT^2} = \frac{WV^2}{2\,gS} = \frac{PT}{S} = \frac{2\,K}{GT^2} = \frac{K}{S} = \sqrt{\frac{2\,PW}{gT}}$$

$$T = \frac{V}{G} = \frac{VW}{gF} = \sqrt{\frac{2\,WS}{gF}} = \sqrt{\frac{2\,S}{G}} = \frac{K}{P} = \sqrt{\frac{2\,WK}{gF^2}}$$

$$G = \frac{gF}{W} = \frac{V}{T} = \frac{V^2}{2\,S} = \frac{2\,S}{T^2} = \frac{gPT}{WS} = \frac{gK}{WS} = \frac{2\,K}{FT^2}$$

$$V = GT = \sqrt{2\,GS} = \frac{2\,S}{T} = \frac{gFT}{W} = \sqrt{\frac{2\,gPT}{W}} = \sqrt{\frac{2\,gK}{W}} = \sqrt{\frac{2\,gSF}{W}}$$

$$S = \frac{VT}{2} = \frac{V^2}{2\,G} = \frac{PT}{F} = \frac{GT^2}{2} = \frac{K}{F} = \frac{gK}{GW} = \frac{gFT^2}{2\,W}$$

$$W = \frac{gF}{G} = \frac{gFT}{V} = \frac{2\,gK}{V^2} = \frac{2\,gFS}{V^2} = \frac{gFT^2}{2\,S} = \frac{gPT^3}{2\,S^2} = \frac{gT^2K}{2\,S^2}$$

$$P = \frac{FS}{T} = \frac{K}{T} = \frac{FV^2}{2\,GT} = \frac{WV^2}{2\,gT} = \frac{2\,WS^2}{gT^3} = \frac{gF^2T}{2\,W}$$

$$K = FS = \frac{FVT}{2} = \frac{FGT^2}{2} = PT = \frac{WV^2}{2\,g} = \frac{GWVT}{2\,g} = \frac{gF^2T^2}{2\,W}$$

Examples: — A body weighing 300 pounds is to be lifted. The velocity with which it is to be hoisted is 3 feet per second, and this velocity is to be reached in 5 seconds. Find the force required for hoisting during the time the motion is accelerated. Here $W = 300$; $V = 3$; $T = 5$. Then, force required for acceleration:

$$F = \frac{VW}{gT} = \frac{3 \times 300}{32.16 \times 5} = 5.6 \text{ pounds.}$$

To this is added the force required to hold the body suspended, or 300 pounds; $300 + 5.6 = 305.6$ pounds.

The force required to move a crane weighing 5000 pounds upon its runways at a uniform speed of 10 feet per second is 200 pounds. What is the force required to start the crane, if this speed is to be acquired in 6 seconds? Here $W = 5000$; $V = 10$; $T = 6$. Then:

$$F = \frac{VW}{gT} = \frac{5000 \times 10}{32.16 \times 6} = 260 \text{ pounds, approx.}$$

To this must be added the 200 pounds required to move the crane at a uniform speed of 10 feet per second, making the total force required during acceleration equal to $260 + 200 = 460$ pounds.

Formulas for Accelerated Rotary Motion

In the following formulas:

F = force in pounds, acting tangentially at end of radius R;
R = radius at end of which F is applied, in feet;
k = radius of gyration in feet;
T = time of acceleration in seconds;
n = revolutions per minute at end of time T;
N = total number of revolutions in time T;
W = weight of revolving body in pounds;
K = work in foot-pounds (or energy) concentrated in revolving body.

From the general formulas for accelerated or retarded motion on the preceding page:

$$F = \frac{VW}{gT}, \text{ from which, for rotary motion, } F = \frac{2\pi knW}{60\,gT}$$

and

$$FR = \frac{Wk \times 2\pi kn}{60\,gT} = \frac{W \times 2\pi k^2 n}{60\,gT}$$

Assuming $g = 32.16$, we have, by substitution:

$$F = \frac{0.00326\,Wnk^2}{TR} = \frac{0.391\,WNk^2}{T^2R} = \frac{60\,K}{3.1416\,RnT} = \frac{K}{6.2832\,RN}$$

$$T = \frac{0.00326\,Wnk^2}{FR} = \sqrt{\frac{0.391\,WNk^2}{FR}} = \frac{60\,K}{3.1416\,RnF} = \frac{0.25\,k\sqrt{WK}}{FR}$$

$$n = \frac{120\,N}{T} = \frac{307.1\,FTR}{Wk^2} = \frac{60\,K}{3.1416\,RTF} = \frac{76.6}{k}\sqrt{\frac{K}{W}}$$

$$N = \frac{Tn}{120} = \frac{2.559\,FT^2R}{Wk^2} = \frac{K}{6.2832\,RF} = \frac{0.64\,T}{k}\sqrt{\frac{K}{W}}$$

$$k = \sqrt{\frac{307.1\,FRT}{WN}} = \sqrt{\frac{2.559\,FRT^2}{WN}} = \frac{0.256\,KT}{N\sqrt{WNFR}} = \frac{337\,K}{n\sqrt{WnTFR}}$$

Example: — A circular disk 18 inches in diameter and weighing 12 pounds revolves about its axis. The revolving force is applied at the end of a lever of 8 inch radius. Find the force required to bring the disk to a speed of 300 revolutions per minute in 10 seconds, friction being neglected.

$$W = 12; \quad R = \tfrac{2}{3}; \quad n = 300; \quad T = 10; \quad k = 0.707 \times \tfrac{3}{4} = 0.53.$$

$$F = \frac{0.00326\,Wnk^2}{TR} = \frac{0.00326 \times 12 \times 300 \times 0.53^2}{10 \times \frac{2}{3}} = 0.49 \text{ pound.}$$

Example: — A flywheel, having an outside diameter of 7 feet and weighing 3000 pounds, is to be brought from a condition of rest to a speed of 200 R.P.M. A belt pull of 100 pounds is available at the periphery of the flywheel rim for this purpose; this belt pull is required entirely for acceleration. If the radius of gyration is assumed to be equal to the mean radius of the flywheel rim, which is 3 feet 3 inches, what time will be required (from rest) to obtain a speed of 200 R.P.M.?

$$F = 100; \quad R = 3.5; \quad k = 3.25; \quad n = 200; \quad W = 3000.$$

Then, time required for acceleration:

$$T = \frac{0.00326\,Wnk^2}{FR} = \frac{0.00326 \times 3000 \times 200 \times 3.25^2}{100 \times 3.5} = 59 \text{ seconds.}$$

Centrifugal Force

Centrifugal Force. — When a body revolves in a curved path, it exerts a force called the *centrifugal force* upon the arm or cord which restrains it from moving in a straight (tangential) line. In the following formulas:

F = centrifugal force in pounds;
W = weight of revolving body in pounds;
v = velocity of revolving body in feet per second;
R = radius of the circle in which the body revolves, (or, in general, radius of gyration), in feet;
n = number of revolutions per minute;
g = acceleration due to gravity = 32.16.

$$F = \frac{Wv^2}{gR} = \frac{Wv^2}{32.16\,R} = \frac{4\,WR\pi^2n^2}{60 \times 60\,g} = \frac{WRn^2}{2933} = 0.000341\,WRn^2$$

$$W = \frac{FRg}{v^2} = \frac{2933\,F}{Rn^2} \qquad v = \sqrt{\frac{FRg}{W}}$$

$$R = \frac{Wv^2}{Fg} = \frac{2933\,F}{Wn^2} \qquad n = \sqrt{\frac{2933\,F}{WR}}$$

(If n is the number of revolutions per second instead of per minute, then $F = 1.227\,WRn^2$.)

For a thin disk or cylinder (emery-wheel, grindstone, etc.), rotating about its center, the resultant of all the centrifugal or radial forces that tend to rupture the disk equals $0.0000767\,WRn^2$, if R is the outside radius of the disk.

Calculating Centrifugal Force. — In the ordinary formula for centrifugal force, $F = 0.000341\,WRn^2$; the mean radius R of the flywheel or pulley rim is given in feet. For small dimensions, it is more convenient to have the formula in the form:

$$F = 0.000028416\,Wrn^2$$

in which F = centrifugal force, in pounds; W = weight of rim, in pounds; r = mean radius of rim, in inches; n = number of revolutions per minute.

In this formula let $C = 0.000028416\,n^2$. This, then, is the centrifugal force of one pound, one inch from the axis. The formula can now be written in the form,

$$F = WrC$$

C is calculated for various values of the revolutions per minute n, and the calculated values of C are tabulated in the accompanying "Table for Calculating Centrifugal Force." To find the centrifugal force in any given case, simply find the value of C in the table and multiply it by the product of W and r, the four multiplications in the original formula given thus having been reduced to two.

Example. — A cast-iron pulley having a mean rim radius of 8 inches and a rim area of 4½ square inches, is to revolve 460 revolutions per minute. Determine the centrifugal force.

The value of C as given in the table for a speed of 460 R.P.M., is 6 approximately; as a cubic inch of cast iron weighs 0.26 pound, the rim weight = $16 \times 3.1416 \times 4\frac{1}{2} \times 0.26$ = 60 pounds nearly; therefore

$$F = 60 \times 8 \times 6 = 2880 \text{ pounds.}$$

Table for Calculating Centrifugal Force

n	C	n	C	n	C	n	C
50.0	0.07104	75	0.15984	125	0.44400	200	1.1367
50.5	0.07247	76	0.16413	126	0.45113	202	1.1595
51.0	0.07391	77	0.16848	127	0.45832	204	1.1826
51.5	0.07537	78	0.17288	128	0.46557	206	1.2059

FLYWHEELS

Flywheels may be classified either as *balance wheels* or as *flywheel pulleys*. The object of all flywheels is to equalize the energy exerted and the work done and thereby prevent excessive or sudden changes of speed. The permissible speed variation is an important factor in all flywheel designs. The allowable speed change varies considerably for different classes of machinery; for instance, it is about 1 or 2 per cent in modern steam engines, while in punching and shearing machinery a speed variation of 20 per cent may be allowed.

As the function of a balance wheel is to absorb and equalize energy in case the resistance to motion, or driving power, varies throughout the cycle, the rim section is generally quite heavy and is designed with reference to the energy that must be stored in it to prevent excessive speed variations and also with reference to the strength necessary to withstand safely the stresses resulting from the required speed. The rims of most balance wheels are either square or nearly square in section, but flywheel pulleys are commonly made wide to accommodate a belt and relatively thin in a radial direction, although this is not an invariable rule.

Flywheels, in general, may either be formed of a solid or one-piece section, or they may be of sectional construction. Flywheels in diameters up to about eight feet are usually cast solid, the hubs being divided in some cases to relieve cooling stresses. Flywheels ranging from, say, eight feet to fifteen feet in diameter, are commonly cast in half sections, and the larger sizes in several sections, the number of which may equal the number of arms in the wheel. The sectional flywheels may be divided into two general classes. One class includes cast wheels which are formed of sections principally because a solid casting would be too large to transport readily. The second class includes wheels of sectional construction which, by reason of the materials used and the special arrangement of the sections, enables much higher peripheral speeds to be obtained safely than would be possible with ordinary sectional wheels of the type not designed especially for high speeds. Various designs have been built to withstand the extreme stresses encountered in some classes of service. The rims in some cases are laminated, being partly or entirely formed of numerous segment-shaped steel plates. Another type of flywheel, which is superior to an ordinary sectional wheel, has a solid cast-iron rim connected to the hub by disk-shaped steel plates instead of cast spokes. Steel wheels may be divided into three distinct types, including (1) those having the center and rim built up entirely of steel plates, (2) those having a cast-iron center and steel rim, and (3) those having a cast-steel center and rim formed of steel plates. Wheels having wire-wound rims have been used to a limited extent when extremely high speeds have been necessary.

When the rim is formed of sections held together by joints it is very important to design these joints properly. The ordinary bolted and flanged rim joints located between the arms average about 20 per cent of the strength of a solid rim and about 25 per cent is the maximum strength obtainable for a joint of this kind. However, by placing the joints at the ends of the arms instead of between them, an efficiency of 50 per cent of the strength of the rim may be obtained. This is due to the fact that the joint is not subjected to the outward bending stresses between the arms but is directly supported by the arm, the end of which is secured to the rim just beneath the joint. When the rim sections of heavy balance wheels are held together by steel links shrunk into place, an efficiency of 60 per cent may be obtained; and by using a rim of box or I-section, a link type of joint connection may have an efficiency of 100 per cent.

Energy Due to Changes of Velocity. — When a flywheel absorbs energy from a variable driving force, as in the case of a steam engine, the velocity increases; and when this stored energy is given out, the velocity diminishes. When the driven member of a machine encounters a variable resistance in performing its work, as when the punch of a punching machine is passing through a steel plate, the flywheel gives up energy while the punch is at work, and, consequently, the speed of the flywheel is reduced. The total energy that a flywheel would give out if brought to a standstill is given by the formula:

$$E = \frac{Wv^2}{2g} = \frac{Wv^2}{64.32}$$

in which E = total energy of flywheel, in foot-pounds;
W = weight of flywheel rim, in pounds;
v = velocity at mean radius of flywheel rim, in feet per second;
g = acceleration due to gravity = 32.16.

If the velocity of a flywheel changes, the energy it will absorb or give up is proportional to the difference between the squares of its initial and final speeds, and is equal to the difference between the energy which it would give out if brought to a full stop and that which is still stored in it at the reduced velocity. Hence:

$$E_1 = \frac{Wv_1^2}{2g} - \frac{Wv_2^2}{2g} = \frac{W(v_1^2 - v_2^2)}{64.32}$$

in which E_1 = energy in foot-pounds which a flywheel will give out while the speed is reduced from v_1 to v_2;
W = weight of flywheel rim, in pounds;
v_1 = velocity at mean radius of flywheel rim before any energy has been given out, in feet per second;
v_2 = velocity of flywheel rim at end of period during which the energy has been given out, in feet per second.

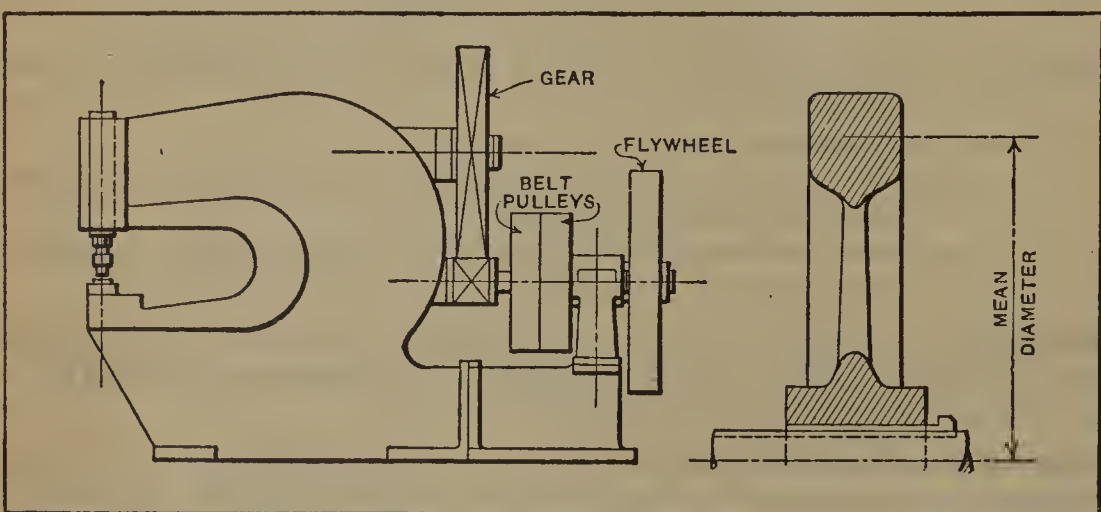
Ordinarily, the effect of the arms and hub does not enter into flywheel calculations, and only the weight of the rim is considered. In computing the velocity, the mean radius of the rim is commonly used.

General Procedure in Flywheel Design. — The general method of designing a flywheel is to determine first the value of E_1 or the energy the flywheel must either supply or absorb for a given change in velocity, which, in turn, varies for different classes of service. The mean diameter of the flywheel may be assumed, or it may be fixed within certain limits by the general design of the machine. Ordinarily the speed of the flywheel shaft is known, at least approximately; the values of v_1 and v_2 can then be determined, the latter depending upon the allowable percentage of speed variation. When these values are known, the weight of the rim and the cross-sectional area required to obtain this weight may be computed. The general procedure will be illustrated more in detail by considering the design of flywheels for punching and shearing machinery.

Flywheels for Presses, Punches, Shears, Etc. — In these classes of machinery, the work that the machine performs is of an intermittent nature and is done during a small part of the time required for the driving shaft of the machine to make a complete revolution. In order to distribute the work of the machine over the entire period of revolution of the driving shaft, a heavy-rimmed flywheel is placed on the shaft, giving the belt an opportunity to perform an almost uniform amount of work during the whole revolution. During the greater part of the revolution of the driving shaft, the belt power is used to accelerate the speed of the flywheel. During the part of the revolution when the work is done, the energy thus stored up in the flywheel is given out at the expense of its velocity. The problem is to determine the weight and cross-sectional area of the rim when the conditions affecting the design of the flywheel are known.

Example: — A flywheel is required for a punching machine capable of punching ¾-inch holes through structural steel plates ¾ inch thick. This machine (see accompanying diagram) is of the general type having a belt-driven shaft at the rear which carries a flywheel and a pinion that meshes with a large gear on the main shaft at the top of the machine. It is assumed that the relative speeds of the pinion and large gear are 7 to 1, respectively, and that the slide is to make 30 working strokes per minute. The preliminary lay-out shows that the flywheel should have a mean diameter (see enlarged detail) of about 30 inches. Find the weight of the flywheel and the size of the rim.

Energy Supplied by Flywheel. — The energy which the flywheel must give up for a given change in velocity, and the weight of rim necessary to supply that energy, must be determined. The maximum pressure for shearing a ¾-inch hole through ¾-inch structural steel equals approximately the circumference of the hole multiplied by the thickness of the stock multiplied by the tensile strength, which is nearly the same as the shearing resistance of the steel. Thus, in this case, $3.1416 \times 3/4 \times 3/4 \times 60{,}000 = 106{,}000$ pounds. The average pressure will be much less than the maximum. Some designers assume that the average pressure is about



one-half the maximum, although experiments show that the material is practically sheared off when the punch has entered the sheet a distance equal to about one-third the sheet thickness. On this latter basis, the average energy E_a in foot-pounds is 2200 in this case. Thus:

$$E_a = \frac{106{,}000 \times 1/3 \times 3/4}{12} = \frac{106{,}000}{4 \times 12} = 2200 \text{ foot-pounds.}$$

If the efficiency of the machine is taken at 85 per cent, the energy required will equal $2200 \div 0.85 = 2600$ foot-pounds nearly. Assume that the energy supplied by the belt while the punch is at work is determined by calculation to equal 175 foot-pounds. Then the flywheel must supply $2600 - 175 \doteq 2425$ foot-pounds $= E_1$.

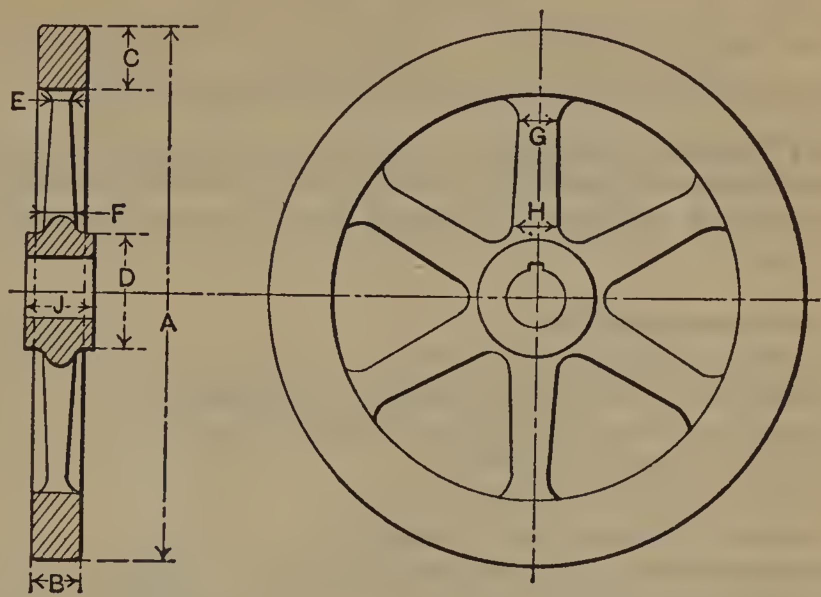
Rim Velocity at Mean Radius. — When the mean radius of the flywheel is known, the velocity of the rim at the mean radius, in feet per second, is:

$$v = \frac{2 \times 3.1416 \times R \times n}{60}$$

in which v = velocity at mean radius of flywheel, in feet per second;
R = mean radius of flywheel rim, in feet;
n = number of revolutions per minute.

Dimensions of Flywheels for Punches and Shears

(Maximum number of revolutions per minute given in table should never be exceeded for cast-iron flywheels.)



A	*B*	*C*	*D*	*E*	*F*	*G*	*H*	*J*	Max. R.P.M.
24	3	3½	6	1¼	1⅜	2¾	3¼	3½	955
30	3½	4	7	1⅜	1½	3	3¾	4	796
36	4	4½	8	1½	1¾	3¼	4¼	4½	637
42	4¼	4¾	9	1¾	2	3½	4½	5	557
48	4½	5	10	1¾	2	3¾	4¾	5½	478
54	4¾	5½	11	2	2¼	4	5	6	430
60	5	6	12	2¼	2½	4½	5½	6½	382
72	5½	7	13	2½	2¾	5	6½	7	318
84	6	8	14	3	3½	5½	7½	8	273
96	7	9	15	3½	4	6	9	9	239
108	8	10	16½	3¾	4½	6½	10½	10	212
120	9	11	18	4	5	7½	12	12	191

According to the preliminary lay-out the mean diameter in this case should be about 30 inches and the driving shaft is to make 210 R.P.M.; hence,

$$v = \frac{2 \times 3.1416 \times 1.25 \times 210}{60} = 27.5 \text{ feet per second.}$$

Weight of Flywheel Rim. — Assuming that the allowable variation in velocity when punching is about 15 per cent, and values of v_1 and v_2 are respectively 27.5 and 23.4 feet per second $(27.5 \times 0.85 = 23.4)$, the weight of a flywheel rim necessary to supply a given amount of energy in foot-pounds while the speed is reduced from v_1 to v_2 would be:

$$W = \frac{E_1 \times 64.32}{v_1^2 - v_2^2} = \frac{2425 \times 64.32}{27.5^2 - 23.4^2} = 750 \text{ pounds.}$$

Size of Rim for Given Weight. — Since 1 cubic inch of cast iron weighs 0.26 pound, a flywheel rim weighing 750 pounds contains $\frac{750}{0.26} = 2884$ cubic inches. The cross-sectional area of the rim in square inches equals the total number of cubic inches divided by the mean circumference, or $\frac{2884}{92.24} = 31$ square inches nearly, which is approximately the area of a rim 5⅛ inches wide and 6 inches deep.

Simplified Flywheel Calculations. — Calculations for designing the flywheels of punches and shears are simplified by the following formulas and the accompanying table of constants applying to different percentages of speed reduction. In these formulas let:

H.P. = horsepower required;
N = number of strokes per minute;
E = total energy required per stroke, in foot-pounds;
E_1 = energy given up by flywheel, in foot-pounds;
T = time in seconds per stroke;
T_1 = time in seconds of actual cut;
W = weight of flywheel rim, in pounds;
D = mean diameter of flywheel rim, in feet;
R = number of revolutions per minute of flywheel before speed reduction;
C and C_1 = values as given in table;
a = width of flywheel rim;
b = depth of flywheel rim;
y = ratio of depth to width of rim.

$$\text{H.P.} = \frac{EN}{33{,}000} = \frac{E}{T \times 550} \qquad E_1 = E\left(1 - \frac{T_1}{T}\right)$$

$$W = \frac{E_1}{CD^2R^2} \qquad a = \sqrt{\frac{1.22\,W}{12\,Dy}} \qquad b = ay$$

For cast-iron flywheels, with a maximum stress of 1000 pounds per square inch:

$$W = C_1E_1 \qquad R = 1940 \div D$$

Values of C and C_1 in the Previous Formulas

Per Cent Reduction	C	C_1	Per Cent Reduction	C	C_1
2½	0.00000213	0.1250	10	0.00000810	0.0328
5	0.00000426	0.0625	15	0.00001180	0.0225
7½	0.00000617	0.0432	20	0.00001535	0.0173

Example 1: — A hot slab shear is required to cut a slab 4 × 15 inches which, at a shearing stress of 6000 pounds per square inch, gives a pressure between the knives of 360,000 pounds. The total energy required for the cut will then be 360,000 × 4/12 = 120,000 foot-pounds. The shear is to make 20 strokes per minute; the actual cutting time is 0.75 second, and the balance of the stroke is 2.25 seconds.

The flywheel is to have a mean diameter of 6 feet 6 inches and is to run at a speed of 200 R.P.M.; the reduction in speed to be 10 per cent per stroke when cutting.

$$H.P. = \frac{120{,}000 \times 20}{33{,}000} = 72.7 \text{ horsepower;}$$

$$E_1 = 120{,}000 \times \left(1 - \frac{0.75}{3}\right) = 90{,}000 \text{ foot-pounds;}$$

$$W = \frac{90{,}000}{0.0000081 \times 6.5^2 \times 200^2} = 6570 \text{ pounds.}$$

Assuming a ratio of 1.22 between depth and width of rim,

$$a = \sqrt{\frac{6570}{12 \times 6.5}} = 9.18 \text{ inches;}$$

$$b = 1.22 \times 9.18 = 11.2 \text{ inches;}$$

or size of rim, say, $9 \times 11\frac{1}{2}$ inches.

Example 2: — Suppose that the flywheel in Example 1 is to be made with a stress of 1000 pounds, due to centrifugal force, per square inch of rim section.

$$C_1 \text{ for 10 per cent} = 0.0328;$$

$$W = 0.0328 \times 90{,}000 = 2950 \text{ pounds.}$$

$$R = \frac{1940}{D}. \quad \text{If } D = 6 \text{ feet, } R = \frac{1940}{6} = 323 \text{ R.P.M.}$$

Assuming a ratio of 1.22 between depth and width of rim, as before:

$$a = \sqrt{\frac{2950}{12 \times 6}} = 6.4 \text{ inches;}$$

$$b = 1.22 \times 6.4 = 7.8 \text{ inches;}$$

or size of rim, say, $6\frac{1}{4} \times 8$ inches.

Stresses in Flywheel Rims. — In general, high speed is desirable for flywheels in order to avoid using wheels which are unnecessarily large and heavy. The stress which tends to rupture a flywheel rim depends solely upon the rim velocity, and is independent of the rim radius, which can be proved as follows: The sum of the centrifugal (radial) forces of the whole rim of a flywheel is:

$$F = \frac{Wv^2}{gR} = \frac{4\,WR\pi^2n^2}{60 \times 60\,g} = 0.000341\,WRn^2$$

where F = centrifugal force, in pounds; W = weight of rim in pounds; R = mean radius of rim in feet, which is approximately equal to radius of gyration; n = revolutions per minute.

The resultant of half of this force tends to disrupt one-half of the rim from the other half. The rupture is resisted by the two sections of the rim at each end of the diameter. The resultant of half the radial forces is to the sum of half of the radial forces as the diameter of the flywheel is to half its circumference, or:

$$\frac{\text{resultant}}{\text{sum of half the radial forces}} = \frac{1}{\frac{1}{2}\pi};$$

Hence,

$$\text{resultant} = \frac{2}{\pi} \times \text{sum of half the radial forces} = \frac{2}{\pi} \times \frac{0.000341\,WRn^2}{2}$$

$$= 0.00010854\,WRn^2.$$

As this resultant force is resisted by the section at each end of the diameter, each section must resist a force

$$S = \frac{0.00010854\, WRn^2}{2} = 0.00005427\, WRn^2.$$

The weight of a rim of cast iron, one square inch in section, is $2\pi R \times 3.125 = 19.635\, R$ pounds, R being in feet. Consequently

$$S = 0.00005427 \times 19.635\, R \times Rn^2 = 0.0010656\, R^2n^2.$$

But as $v = \frac{2\pi Rn}{60}$, and $v^2 = \frac{4\pi^2R^2n^2}{3600}$, where v = velocity of rim in feet per second, it follows that

$$S = \frac{0.0010656\, v^2 \times 3600}{4\pi^2} = 0.0972\, v^2.$$

Thus the stress S in the flywheel rim is independent of the radius and depends only on the rim velocity.

Relation between Centrifugal Force and Disruptive Force in a Flywheel Rim. — When the total centrifugal force has been calculated for a flywheel rim, the result is analogous to that obtained when the total internal pressure acting on a certain length of a section of a steam boiler shell is figured. The total centrifugal force, therefore, is not equal to the disruptive force tending to tear the rim apart. For example, the total internal pressure on a 1-inch long section of a boiler shell, 50 inches in diameter (157 inches in circumference), with a pressure of 100 pounds per square inch, is 15,700 pounds. The actual bursting or tangential stress is $15{,}700 \div 3.1416 = 5000$ pounds. This bursting stress is resisted by two thicknesses of the shell, one on each side. In the case of the flywheel, the total centrifugal force developed in the rim must be divided by 3.1416 to get the measure of the disruptive force.

Thickness of Flywheel Rims. — A mathematical analysis of the stresses in flywheel rims is not conclusive owing to the uncertainty of shrinkage stresses in castings or the strength of the joint in the case of sectional wheels. When a flywheel of ordinary design is revolving at high speed, the tendency of the rim is to bend or bow outward between the arms, and the bending stresses may be serious, especially if the rim is wide and thin and the spokes are rather widely spaced. When the rims are thick, this tendency does not need to be considered, but in the case of a thin rim, running at a high rate of speed, the stress in the middle might become sufficiently great to cause the wheel to fail. The proper thickness of a cast-iron rim to resist this tendency is given for solid rims by the formula:

$$t = \frac{0.475\, d}{n^2\left(\frac{6000}{v^2} - \frac{1}{10}\right)}$$

For a jointed rim, the formula is:

$$t = \frac{0.95\, d}{n^2\left(\frac{6000}{v^2} - \frac{1}{10}\right)}$$

In these formulas, t = thickness of rim, in inches; d = diameter of flywheel, in inches; n = number of arms; v = peripheral speed, in feet per second.

Safe Speeds for Flywheels. — One hundred feet per second may be regarded as a safe rim speed for cast-iron wheels made in one piece, providing the design is such that there are no severe shrinkage strains in the casting. Ordinarily, there are strains, and, therefore, about 85 feet per second is as high a rim speed as should be considered good practice. If the wheel is made in halves or sections, the efficiency of the rim joint must be taken into consideration. A steel-casting flywheel made in one piece and free from shrinkage strains should run with safety at the rim speed of 200 feet per second. It should be noted that the stress in the rim increases with the square of the speed, so that even a small increase in speed causes a considerable increase in the stress.

Safe speeds for flywheels are given in the accompanying tables. The safe speeds for cast-iron flywheels with solid rims are based on a rim speed of 5280 feet per minute, or 88 feet per second. The second table of safe speeds for cast-iron flywheels with jointed rims is based on a maximum efficiency of 25 per cent for flanged joints, 50 per cent for pad joints, and 60 per cent for link joints. These speeds are recommended by the flywheel insurance department of the Fidelity & Casualty Co. of New York.

As the stresses in the rim due to centrifugal force increase with the square of the speed, a relatively slight increase in speed may be dangerous and even cause the wheel to burst or "explode." The margin of safety on speed is the square root of the factor of safety for strength. If the speed should be tripled, the rim stress would be nine times as great as before, and in the case of a flywheel originally designed with a strength factor of safety of 27 for normal speed, this factor would be reduced to 3 if the speed were tripled. If a sectional wheel having flanged and bolted joints located between the arms had a factor of safety of 12 in the solid rim for normal speeds, the factor for the joints would be 3 or less at normal speeds, since the average strength of such joints is only about one-fifth to one-fourth the strength of the rim; therefore, in this case the flywheel would be liable to burst if the speed were increased only 73 per cent, and comparatively few flywheels have as large a margin of safety as this.

Since the material which has the greatest strength for a given weight will withstand the highest speed, wood is in this respect a better material for flywheels than cast-iron, and it has been used to some extent for large wheels. A well-constructed maple wheel may be run safely at a rim speed of 150 feet per second, provided the wheel is not made in halves or sections with rim joints which permit taking the wheel apart. The wooden rims are built up of segments which are sawed so as to obtain as much of the straight grain of the wood as possible.

Safe Speeds for Cast-iron Flywheels with Jointed Rims*

* If the revolutions given in the table be increased 20 per cent the margin of safety on speed will be reduced to *two and one-half;* if the revolutions be increased 50 per cent the margin of safety will be reduced to *two.*

Factors of Safety for Flywheels. — Cast-iron flywheels commonly have a factor of safety of 10. When flywheel rims are made of wood, the full tensile strength of the wood is not obtained, and partly for this reason a factor of safety of 20 is used for wood. In the case of a wooden rim, the real factor of safety is less than 20, because part of the tensile strength is lost in sawing, and on account of the joints between the segments.

Wheels do not often fail from torsional stress or from twisting action in pulling their load, because enough material can be put in the wheel to resist successfully any load required. There is, however, no possible way to overcome the centrifugal force due to speed. Increasing the thickness of the rim of the wheel does not strengthen it so far as centrifugal force is concerned, because the weight added also increases the centrifugal force, leaving the wheel no stronger than before. There is, therefore, a definite speed at which any wheel, however sound, will explode, regardless of the amount of material it contains.

Tests to Determine Flywheel Bursting Speeds. — Tests made by Prof. C. H. Benjamin, to determine the bursting speeds of flywheels, showed the following results:

Cast-iron Wheels with Solid Rims. — Cast-iron wheels having solid rims burst at a rim speed of 395 feet per second, corresponding to a centrifugal tension of about 15,600 pounds per square inch.

Wheels with Jointed Rims. — Four wheels were tested with joints and bolts inside the rim, after the familiar design ordinarily employed for band wheels, but with the joints located at points one-fourth of the distance from one arm to the next, these being the points of least bending moment, and, consequently, the points at which the deflection due to centrifugal force would be expected to have the least effect. The tests, however, did not bear out this conclusion. The wheels burst at a rim speed of 194 feet per second, corresponding to a centrifugal tension of about 3750 pounds per square inch. These wheels, therefore, were only about one-quarter as strong as the wheels with solid rims, and burst at practically the same speed as wheels in a previous series of tests in which the rim joints were midway between the arms. This is doubtless due to the fact that the heavy mass of the flanges and bolts locates the bending moment near them. In these wheels the combined tensile strength of the bolts in the flange joints was slightly less than one-third the strength of the rim, which is about the maximum ratio possible with this style of joint.

Bursting Speed for Link Joints. — Another type of wheel with deep rim, fastened together at the joints midway between the arms by links shrunk into recesses, after the manner of flywheels for massive engines, gave much superior results. This wheel burst at a speed of 256 feet per second, indicating a centrifugal tension of about 6600 pounds per square inch.

Wheel having Tie-rods. — Tests were made on a band wheel having joints inside the rim, midway between the arms, and in all respects like others of this design previously tested, except that tie-rods were used to connect the joints with the hub. It burst at a speed of 225 feet per second, showing an increase of strength of from 30 to 40 per cent over similar wheels without the tie-rods.

Wheel Rim of I-section. — Several wheels of special design, not in common use, were also tested, the one giving the greatest strength being an English wheel, with solid rim of I-section, made of high-grade cast iron and with the rim tied to the hub by steel wire spokes. These spokes were adjusted to have a uniform tension by "tuning," and the wheel gave way at a rim speed of 424 feet per second, which is slightly higher than the speed of rupture of the solid rim wheels with ordinary style of spokes.

Bursting Speeds of Cast-iron Pulleys. — The pulley tested was of cast iron, well proportioned, and of the type used on shafting for transmitting power. It was 48 inches in diameter, had six arms and weighed 194 pounds. The rim was whole and was 8½ inches wide and about ⅜ inch thick, finished on the outside. The arms were elliptical in section, 3⅛ inches by 1 1/16 inch at the hub, and 2 inches by ¾ inch at the rim. On the whole the wheel was well designed and showed no signs of shrinkage strains. It had, however, been balanced by riveting a cast-iron washer inside the rim at the lighter side. The pulley burst at a speed of 1100 revolutions per minute, the linear speed of the rim at rupture being 230 feet per second.

Wheel No. 2 was a cast-iron pulley of the same general style and dimensions as No. 1, but with a split hub and rim. The flanges were located midway between the arms and bolted at some little distance inside the rim; thus the joints were in the worst possible position to withstand the bending action due to centrifugal force, and their own weight only aggravated the difficulty. The flanges weighed with their bolts 7½ pounds. This wheel burst at less than 700 revolutions per minute, the tachometer not recording below this speed. It was estimated that the speed was only about 600 revolutions per minute. At 600 revolutions per minute the linear speed of the rim would be only 125 feet per second.

Tests on Flywheel of Special Construction. — The third test was on a flywheel 49 inches in diameter and weighing about 900 pounds. The rim was 6¾ inches wide and 1⅛ inches thick, and was built of ten segments, the material being steel casting. Each joint was secured by three "prisoners" of an I-section on the outside face, by link prisoners on each edge, and by a dovetailed bronze clamp on the inside, fitting over lugs on the rim. The arms were of phosphor-bronze, twenty in number, ten on each side, and were a cross in section. These arms came midway between the rim joints and were bolted to plane faces on the polygonal hub. The rim was further reinforced by a system of diagonal bracing, each section of the rim being supported at five points on each side, in such a way as to relieve it almost entirely from bending. The braces, like the arms, were of phosphor-bronze, and all bolts and connecting links of steel. This wheel was designed as a model of a proposed 30-foot flywheel. On account of the excessive air resistance the wheel was enclosed at the sides between sheet-metal disks. This wheel burst at 1775 revolutions per minute or at a linear speed of 372 feet per second. The hub and main spokes of the wheel remained nearly in place, but parts of the rim were found two hundred feet away. This sudden failure of the rim casing was unexpected, as it was thought the flange bolts were the parts to give way first. The tensile strength of the casing at the point of fracture was about four times the strength of the wheel rim at a solid section.

Bursting Speeds of Disks. — Let N = bursting speed of a disk in revolutions per minute; S = ultimate tensile strength of material in pounds per square inch; R = outside radius of disk; r = radius of bore or hole in disk; w = weight of material in pounds per cubic inch; $g = 32.16$. Then:

$$N = \frac{180}{3.1416}\sqrt{\frac{Sg}{(R^2 + Rr + r^2)\,w}} = 57.3\sqrt{\frac{32.16\,S}{(R^2 + Rr + r^2)\,w}}$$

Steam Engine Flywheels. — The variable amount of energy during each stroke and the allowable percentage of speed variation are of especial importance in designing steam engine flywheels. The earlier the point of cut-off, the greater the variation in energy and the larger the flywheel that will be required. The weight of the reciprocating parts and the length of the connecting-rod also affect the variation. The following formula is used for computing the weight of the flywheel rim:

Let W = weight of rim in pounds;
D = mean diameter of rim in feet;
N = number of revolutions per minute;
$\frac{1}{n}$ = allowable variation in speed (from 1/50 to 1/100);
E = excess and deficiency of energy in foot-pounds;
c = factor of energy excess, from the accompanying table;
H.P. = indicated horsepower.

Then, if the indicated horsepower is given:

$$W = \frac{387{,}587{,}500 \times cn \times \text{H.P.}}{D^2N^3} \tag{1}$$

If the work in foot-pounds is given, then:

$$W = \frac{11{,}745\, nE}{D^2N^2} \qquad (2)$$

In the second formula, E equals the average work in foot-pounds done by the engine in one revolution, multiplied by the decimal given in the accompanying

Factors for Engine Flywheel Calculations

Condensing Engines						
Fraction of stroke at which steam is cut off........	1/3	1/4	1/5	1/6	1/7	1/8
Factor of energy excess...	0.163	0.173	0.178	0.184	0.189	0.191

Non-condensing Engines				
Steam cut off at........................	1/2	1/3	1/4	1/5
Factor of energy excess...................	0.160	0.186	0.209	0.232

table, "Factors for Engine Flywheel Calculations," which covers both the condensing and non-condensing engines:

Example 1. — A non-condensing engine of 150 indicated horsepower is to make 200 revolutions per minute, with a speed variation of 2 per cent. The average cut-off is to be at one-quarter stroke, and the flywheel is to have a mean diameter of 6 feet. Required, the necessary weight of rim in pounds.

From the table $c = 0.209$, and from the data given H.P. = 150; $N = 200$; $\frac{1}{n} = 1/50$ or $n = 50$; $D = 6$.

Substituting these values in equation (1):

$$W = \frac{387{,}587{,}500 \times 0.209 \times 50 \times 150}{6^2 \times 200^3} = 2110 \text{ pounds, nearly.}$$

Example 2. — A condensing engine, 24×42 inches, cuts off at one-third stroke and has a mean effective pressure of 50 pounds per square inch. The flywheel is to be 18 feet in mean diameter and make 75 revolutions per minute with a variation of 1 per cent. Required, weight of rim.

The work done on the piston in one revolution is equal to the pressure on the piston multiplied by the distance traveled or twice the stroke in feet. The area of the piston in this case is 452.4 square inches, and twice the stroke is 7 feet. The work done on the piston in one revolution is, therefore, $452.4 \times 50 \times 7 = 158{,}340$ foot-pounds. From the table $c = 0.163$, and therefore:

$$E = 158{,}340 \times 0.163 = 25{,}810 \text{ foot-pounds.}$$

From the data given: $n = 100$; $D = 18$; $N = 75$. Substituting these values in equation (2):

$$W = \frac{11{,}745 \times 100 \times 25{,}810}{18^2 \times 75^2} = 16{,}650 \text{ pounds, nearly.}$$

Spokes or Arms of Flywheels. — Flywheel arms are usually of elliptical cross-section. The major axis of the ellipse is in the plane of rotation to give the arms greater resistance to bending stresses and reduce the air resistance which may be considerable at high velocity. The stresses in the arms may be severe, due to the inertia of a heavy rim when sudden load changes occur. The strength of the arms should equal three-fourths the strength of the shaft in torsion.

If W equals the width of the arm at the hub (length of major axis) and D equals the shaft diameter, then W equals 1.3 D for a wheel having 6 arms; and for an 8-arm wheel W equals 1.2 D. The thickness of the arm at the hub (length of minor axis) equals one-half the width. The arms usually taper toward the rim. The cross-sectional area at the rim should not be less than two-thirds the area at the hub.

Flywheels for Motor-driven Planers. — The primary function of a flywheel for a motor-driven planer is not so much for maintaining a constant speed as relieving the motor from excessive shocks at the points of reversal. Tests made at the Worcester Polytechnic Institute with a 36- by 36- by 10-foot planer driven by a 10-horsepower induction motor showed a current consumption of 1.85 kilowatt-hour when no flywheel was used and the length of the stroke was five feet. With a ten-foot stroke, the consumption was 1.63 kilowatt-hour without a flywheel. When a flywheel was used, the consumption was 1.3 and 1.24 kilowatt-hour, respectively, for the two lengths of stroke mentioned. Thus, with the flywheel, 29.5 per cent less power was required with the short stroke, and 24 per cent less power with the long stroke. The flywheel was also an advantage in increasing the average rate of production and preventing "slow-downs" and tardy reversals.

Critical Speed of Rotating Body. — If a body or disk mounted upon a shaft rotates about it, the center of gravity of the body or disk must be at the center of the shaft, if a perfect running balance is to be obtained. In most cases, however, the center of gravity of the disk will be slightly removed from the center of the shaft, owing to the difficulty of perfect balancing. Now, if the shaft and disk be rotated, the centrifugal force generated by the heavier side will be greater than that generated by the lighter side geometrically opposite to it, and the shaft will deflect toward the heavier side, causing the center of the disk to rotate in a small circle. These conditions hold true up to a comparatively high speed; but a point is eventually reached (at several thousand revolutions per minute) when momentarily there will be excessive vibration, and then the parts will run quietly again. The speed at which this occurs is called the *critical speed* of the wheel, and the phenomenon itself is called the *settling* of the wheel. The explanation of the settling is that at this speed the axis of rotation changes, and the wheel and shaft, instead of rotating about their geometrical center, begin to rotate about an axis through their center of gravity. The shaft itself is then deflected so that for every revolution its geometrical center traces a circle around the center of gravity of the rotating mass.

Critical speeds depend upon the magnitude or location of the load or loads carried by the shaft, the length of the shaft, its diameter and the kind of supporting bearings. The normal operating speed of a machine may or may not be higher than the critical speed. For instance, some steam turbines exceed the critical speed, although they do not run long enough at the critical speed for the vibrations to build up to an excessive amplitude. The practice of the General Electric Co. at Schenectady is to keep below the critical speeds. It is assumed that the maximum speed of a machine may be within 20 per cent of the critical speed without vibration troubles. Thus, in a design of steam turbine sets, critical speed is a factor that determines the size of the shafts, both for the generators and turbines. While a machine may run very close to the critical speed, the alignment and play of the bearings, the balance and construction generally, will require extra care, resulting in a more expensive machine; moreover, while such a machine may run smoothly for a considerable time, any looseness or play that may develop later, causing a slight unbalance, will immediately set up excessive vibrations.

Formulas for Critical Speeds. — The critical speed formulas given in the accompanying table (from the paper on Critical Speed Calculation presented

Critical Speed Formulas

Formulas for Single Concentrated Load

 $N = 387{,}000 \dfrac{d^2}{ab}\sqrt{\dfrac{l}{W}}$ Bearings supported	 $N = 1{,}550{,}500 \dfrac{d^2}{l\sqrt{Wl}}$ Bearings supported	 $N = 387{,}000 \dfrac{d^2 l}{ab}\sqrt{\dfrac{l}{Wab}}$ Bearings fixed
 $N = 3{,}100{,}850 \dfrac{d^2}{l\sqrt{Wl}}$ Bearings fixed	 $N = 775{,}200 \dfrac{d^2 l}{ab}\sqrt{\dfrac{l}{Wa(3l+b)}}$ One fixed — One supported	 $N = 387{,}000 \dfrac{d^2}{l\sqrt{Wl}}$ One fixed — One free end

Formulas for Distributed Loads — First Critical Speed

 $N = 2{,}232{,}500 \dfrac{d^2}{l\sqrt{Wl}}$ $N_1 = 4{,}760{,}000 \dfrac{d}{l^2}$ Bearings supported	 $N = 4{,}979{,}250 \dfrac{d^2}{l\sqrt{Wl}}$ $N_1 = 10{,}616{,}740 \dfrac{d}{l^2}$ Bearings fixed	 $N = 795{,}200 \dfrac{d^2}{l\sqrt{Wl}}$ $N_1 = 1{,}695{,}500 \dfrac{d}{l^2}$ One fixed — One free end

N = critical speed, R.P.M.; N_1 = critical speed of shaft alone; d = diameter of shaft, in inches; W = load applied to shaft, in pounds; l = distance between centers of bearings, in inches; a and b = distances from bearings to load.

before the A.S.M.E. by S. H. Weaver) apply to (1) shafts with single concentrated loads and (2) shafts carrying uniformly distributed loads. These formulas also cover different conditions as regards bearings. If the bearings are self-aligning or very short, the shaft is considered supported at the ends; whereas, if the bearings are long and rigid, the shaft is considered fixed. These formulas, for both concentrated and distributed loads, apply to vertical shafts as well as horizontal shafts, the critical speeds having the same value in both cases. The data required for the solution of critical speed problems are the same as for shaft deflection. As the shaft is usually of variable diameter and its stiffness is increased by a long hub, an ideal shaft of uniform diameter and equal stiffness must be assumed.

In calculating critical speeds, the weight of the shaft is either neglected or, say, one-half to two-thirds of the weight is added to the concentrated load. The formulas apply to steel shafts having a modulus of elasticity $E = 29{,}000{,}000$. While a shaft carrying a number of loads or a distributed load may have an infinite number of critical speeds, ordinarily it is the first critical speed that is of importance in engineering work, which is the speed obtained by the formulas given in the table for distributed loads.

Angular Velocity. — The angular velocity of a rotating body is expressed in angular measure and equals the angle through which any radius of the body turns in one second. This angle is generally expressed in radians.

$$\text{One radian} = \frac{180}{\pi} = \frac{180}{3.1416} = 57.3 \text{ degrees.}$$

The angular velocity is generally denoted by the Greek letter ω. Let ω = angular velocity in radians; r = radius of revolving body in feet; n = number of revolutions per minute; v = velocity of a point on the periphery, in feet per second; then,

$$v = \frac{2\pi r n}{60}; \quad \omega = \frac{v}{r} = \frac{2\pi n}{60}; \quad v = \omega r.$$

Example: — A flywheel, 12 feet in diameter, revolves at 60 revolutions per minute. Find the angular velocity ω. Here, $r = 6$; $n = 60$.

$$\omega = \frac{2 \times 3.1416 \times 60}{60} = 6.2832 \text{ radians.}$$

The table of angular velocity gives this velocity directly in radians for all numbers of revolutions per minute from 1 to 499. The method in which this table is used may be best explained by an example: Find the angular velocity in radians of a flywheel making 97 revolutions per minute. Locate 90 in the left-hand column and 7 at the top of the columns; at the intersection of the two lines, the angular velocity is read off as equal to 10.16 radians.

The Pendulum

A *simple pendulum* is a material point which is supposed to be suspended from a fixed point by a string without weight. A *compound pendulum* is a material body suspended from a fixed axis about which it oscillates by the force of gravity. The center of oscillation is the point at which, if all the matter in the compound pendulum were concentrated there, it would make a simple pendulum which would oscillate in the same periods of time. The angle included between the extreme positions of the line drawn from the point of suspension to the center of oscillation, is called the angle of oscillation. The time of vibration of a pendulum varies directly as the square root of the length and inversely as the square root of the acceleration due to gravity at the given latitude and elevation above the earth's surface. Hence, there is a definite length of a simple pendulum that vibrates seconds at any given place. At New York this length is 39.1017 inches or 3.2585 feet. In the formulas in the tables: l = the length of simple pendulum or distance between point of suspension and center of oscillation, in inches; t = time in seconds for n oscillations; n = number of single oscillations in time t.

Simple Pendulum

	$l = \frac{12\,gt^2}{\pi^2 n^2} = \frac{39.1\,t^2}{n^2}$ $t = \frac{n\sqrt{l}}{6.25}$ $n = \frac{6.25\,t}{\sqrt{l}}$		A, center of gravity. B, center of gyration. C, center of oscillation. $a : b = b : l$ $b = \sqrt{al} = 1.155\,a$ $l = 1\tfrac{1}{3}\,a$

Compound Pendulum

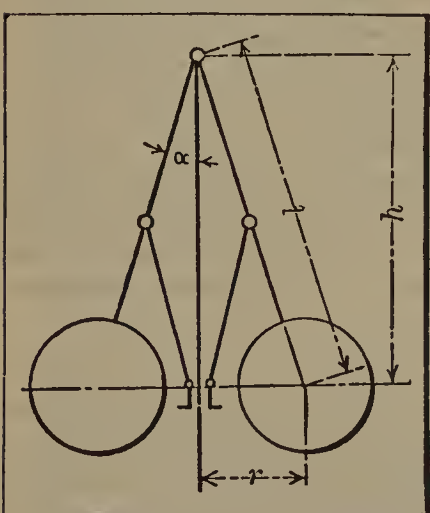
	W and w, weights in pounds. P, point of suspension. $l = \frac{a^2W + b^2w}{aW + bw}$		W and w, weights in pounds. P, point of suspension. A, center of gravity. $c = \frac{aW - bw}{W + w}$ $l = \frac{a^2W + b^2w}{c\,(W + w)}$

Conical Pendulum. — If a weight suspended by a cord revolves at a uniform speed along the circumference of a circle in a horizontal plane, this weight forms a conical pendulum and is held in equilibrium by three forces; the tension in the cord, the centrifugal force, and the force of gravity. Let r be the radius of the circular path in feet which the weight follows; h, the distance in feet of the plane in which the weight moves from the point of suspension; v, the velocity in feet per second of the center of gravity of the weight. Then, time t, in seconds for one revolution, is:

$$t = \frac{2\pi r}{v} = 6.283\sqrt{\frac{h}{g}} \qquad h = \frac{gt^2}{4\pi^2} = 0.8146\,t^2$$

The principle of the conical pendulum is employed in the design of fly-ball governors for steam engines.

Application to Governors. — In the following formulas:



n = number of revolutions per minute;
g = acceleration due to gravity = 32.16;
α = angle made by the arm with the vertical axis;
h = vertical distance from center of ball to point of suspension, in feet;
l = length of arm, in feet.

$$n = \frac{60}{2\pi}\sqrt{\frac{g}{h}} = \frac{54.16}{\sqrt{h}} = \frac{54.16}{\sqrt{l \cos \alpha}}$$

$$h = \frac{2933}{n^2}.$$

Example: — In a governor, of the type shown in the illustration, the balls fly out so that angle α = 45 degrees; how many revolutions per minute are the balls making, if l = 6 inches?

$$n = \frac{54.16}{\sqrt{\frac{1}{2} \times \cos 45^\circ}} = 91.1 \text{ rev. per minute.}$$

Engine Governors. — Governors may be of a purely centrifugal type such as the fly-ball or pendulum design previously referred to, or the principle of inertia may be introduced to secure better speed regulation. Thus, there are two general classes of governors known as centrifugal and inertia governors. The method of utilizing the motion of the governing element for regulating the speed varies; as applied to steam engines, there is the general type of governor which controls the speed by operating a throttling valve which increases or diminishes the amount of steam admitted to the steam-chest, and another general type which regulates the speed by changing the point of cut-off and consequently the amount of expansion in the cylinders.

In the design of governors, the sensitiveness, effort, and stability of the governor are important factors. The sensitiveness of a fly-ball governor is indicated by the amount that the governing sleeve is displaced for a given change in speed, the displacement being relatively large for a given speed change if the governor is sensitive.

The term "effort" as applied to a governor relates to the energy it is capable of exerting upon the governing mechanism. Thus, in the case of a fly-ball governor, the effort indicates the energy exerted on the sleeve while the governor speed is increasing or diminishing. If the energy stored in a revolving governor is small, its sensitiveness will be reduced, because a larger speed change is necessary to obtain the power for operating the governing mechanism than would be required with a governor which exerts greater energy for a given speed change.

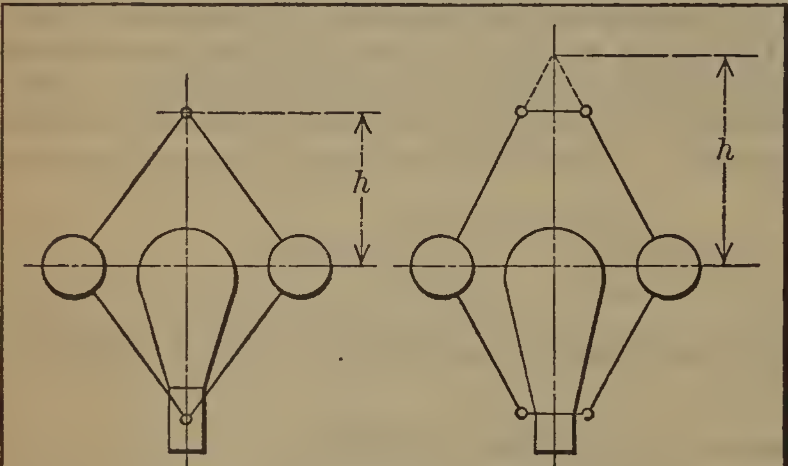


FIG. 1. FIG. 2.

When a governor occupies a definite position of equilibrium for any speed within the range of speeds controlled by the governor, it is said to be "stable." If the load on an engine having a fly-ball governor is diminished, the balls of a stable governor will move outward to a new position as the speed increases, although there will usually be a temporary oscillating movement on each side of this new position, the oscillations gradually diminishing. If the governor were instable (and therefore useless) the oscillations would increase until the limiting points were reached.

Loaded or Weighted Fly-ball Governors. — As the arms of a governor of the conical pendulum type swing outward toward the horizontal position as the result of increasing speed, the change in height h (see Fig. 1) is small for given changes in speed. For instance, if the speed is changed from 50 to 70 revolutions per minute, the difference between the values of h is nearly 7 inches, whereas if the speed changes from 200 to 300 revolutions per minute, the difference in height h for the two speeds is only about ½ inch. Hence, the simple pendulum governor is not suitable for the higher speeds, because then the movement which accompanies the speed changes is too small to secure proper regulation through the governing mechanism. Fly-ball governors are adapted for much higher speeds by loading them. The load may be in the form of a weight which surrounds the spindle, as illustrated by Fig. 1. This is known as a Porter governor.

In the following formula, w = the weight of one governor ball in pounds; e = the weight of the additional load; h = the height in feet indicated by the diagram, Fig. 1; n = speed of governor in revolutions per minute:

$$h = \frac{2933}{n^2} \times \frac{e+w}{w}$$

If the governor is constructed as indicated by the diagram Fig. 2, the height h is not measured from the points at which the arms or rods are suspended, but from the point where the axes of the rods intersect with the vertical center line. The outward movement of the balls may be resisted by a spring instead of a weight, as in the case of the Hartnell governor, which is known as a spring-loaded type.

Sensitiveness and Stability of Governors. — The sensitiveness of one governor may be compared with that of another by determining the *coefficient of speed variations*. If C = the coefficient of speed variations, M = maximum speed within limits of the governor action; M_1 = minimum speed within limits of governor action; m = mean speed within these limits; then,

$$C = \frac{M - M_1}{m}$$

The minimum value of coefficient C necessary to obtain stability in a pendulum type of governor is given by the following formula in which y = distance the fly-balls move horizontally in feet; F = mean centrifugal force of fly-balls in pounds; H = indicated horsepower of engine; W = the weight of engine flywheel in pounds; S = revolutions per minute of main shaft; R = the flywheel radius in feet.

$$C = 4000 \sqrt[3]{\frac{xy}{F}} \times \sqrt[3]{\frac{H^2}{S^4R^4W^2}}$$

The factor x in this formula represents that weight which would be equivalent to the weights of the various moving parts, if it were centered at a point corresponding to the center of gravity of the fly-balls. To determine the value of x, first determine the weights of the different moving parts of the governor, such as the balls, the central weight or load (in the case of a Porter governor), the sleeve, etc.; multiply the weight of each part by the square of the distance it moves from one position to the other; add the various products thus obtained, and divide the total sum by the square of the corresponding movement of the fly-balls at right angles to the governor spindle.

Shaft Governors. — Shaft governors are so named because the governing mechanism is carried by the main shaft and is commonly attached in some way to the flywheel. One type is so arranged that, in the case of a steam engine, the action of centrifugal force on a pivoted and weighted lever, to which a spring is attached, changes the position of the eccentric which operates the slide valve, thus increasing or decreasing the valve travel and changing the point of cut-off. Another type is so designed that the inertia of a pivoted "weight arm" accelerates the governing action by acting in conjunction with the effect of centrifugal force, thus increasing the sensitiveness of the governor. With the inertia governor, the effort or force needed to actuate the governing mechanism increases as the rate of velocity change increases; hence this type is adapted to engines liable to sudden load changes. When the load remains practically constant, the centrifugal type of shaft governor is often employed in preference to the inertia type. The design of these governors depends upon the arrangement of the governing mechanism and upon varying factors.

STRENGTH OF MATERIALS

Elastic Limit; Modulus of Elasticity. — When external forces act upon a material, they produce tension, compression, bending, shearing, or torsional stresses within the material. In most instances, a combination of two or more of these stresses is produced. All stresses to which a material is subjected cause a deformation in it. If the stress is not too great, however, the material will return to its original shape and dimensions when the external stress is removed. The property which enables a material to return to its original shape and dimensions is called its *elasticity*. If a material has been stressed to such an extent that, upon the removal of the load, it does not fully return to its original shape and dimensions, its *elastic limit* has been exceeded. Up to the elastic limit the deformation is directly proportional to the load. The elastic limit is defined as the point at which the deformation ceases to be proportional to the stress. This point, however, is difficult to determine with accuracy.

The *modulus of elasticity* of a material is the quotient obtained by dividing the stress per square inch by the elongation in one inch caused by this stress. The modulus of elasticity is generally denoted by E. If an elongation of 0.015 inch is produced in a steel bar, ten inches long, by a load of 45,000 pounds per each square inch of cross-section of the bar, then the modulus of elasticity will be:

$$E = \frac{45{,}000}{0.0015} = 30{,}000{,}000.$$

As the elongation is assumed to be proportional to the load up to the elastic limit, the modulus of elasticity of a material may be used for finding the elongation e produced by any load per square inch, S, or: $e = S \div E$.

For example, the modulus of elasticity of wrought iron is 27,000,000. Find the elongation per inch produced by a stress of 15,000 pounds per square inch.

$$e = 15{,}000 \div 27{,}000{,}000 = 0.00055 \text{ inch}.$$

Factor of Safety. — The factor of safety may be considered as the product of four primary factors which may be designated as factors a, b, c and d. Designating the factor of safety by F,

$$F = a \times b \times c \times d.$$

The first of these factors a is the ratio of the ultimate strength of the material to the elastic limit, meaning, in this case, by the elastic limit, that boundary line within which the material is perfectly elastic and takes no permanent set. For ordinary materials, the factor a is 2; for nickel steel and oil tempered forgings, it is reduced to 1½.

The second factor b depends on the character of the stress within the material. This factor is 1, for a dead load; 2, for a load varying between zero and maximum; and 3, for a load which produces alternately a tension and a compression equal in amount.

The third factor c depends upon the manner in which the load is applied to the piece under stress. For a load gradually applied, this factor is 1. For a load suddenly applied, the factor is 2. If the load is applied not only suddenly but with impact, this factor must be still further increased in value. (See "Stresses in Beams Produced by Shocks.")

The last factor d may be called the factor of ignorance. The other factors provide against known conditions and this provides against the unknown. It commonly varies in value between 1½ and 3 and occasionally should be given as high a value as 10. It provides against accidental overload, against unexpectedly severe service and unreliable or imperfect materials, etc. When all the conditions are thoroughly known and there is no danger of overload, this factor may be made equal to 1½ for wrought iron and mild steel, and 2, for cast iron.

As an example of the use of the formula given for the factor of safety, find the factor of safety that ought to be used for a forged steel steam-engine piston-rod. The elastic limit will probably be slightly more than one-half the ultimate strength; hence, $a = 2$. The rod will be alternately in tension and compression; hence, $b = 3$. The steam pressure will be applied suddenly or nearly so; hence, $c = 2$. The material is of a reliable kind; hence, $d = 1\frac{1}{2}$. Then:

$$F = 2 \times 3 \times 2 \times 1\tfrac{1}{2} = 18.$$

A table of factors of safety determined by the analytical method outlined, is given herewith.

Table of Factors of Safety

Class of Service	Factors				
	a	*b*	*c*	*d*	*F*
Boilers	2	1	1	2¼–3	4½– 6
Piston-and connecting-rods for double-acting engines	1½–2	3	2	1½	13½–18
Piston- and connecting-rod for single-acting engines	1½–2	2	2	1½	9–12
Shaft carrying bandwheel, flywheel, or armature	1½–2	3	1	1½	6¾– 9
Lathe spindles	2	2	2	1½	12
Mill shafting	2	3	2	2	24
Steel work in buildings	2	1	1	2	4
Steel work in bridges	2	1	1	2½	5
Steel work for small work	2	1	2	1½	6
Cast-iron wheel rims	2	1	1	10	20
Steel wheel rims	2	1	1	4	8
Materials	**Minimum Values**				
Cast-iron and other castings	2	1	1	2	4
Wrought iron or mild steel	2	1	1	1½	3
Oil tempered or nickel steel	1½	1	1	1½	2¼
Hardened steel	1½	1	1	2	3
Bronze and brass, rolled or forged	2	1	1	1½	3

Strength and Properties of Tobin Bronze. — This special bronze contains from 59 to 63 per cent of copper, from ½ to 1½ per cent of tin, the remainder being zinc. It has a specific gravity of 8.4, the weight per cubic inch being 0.304 pound. On account of its tensile strength and its resistance to the corrosive action of sea water, it is used to a great extent in marine engineering. The ultimate tensile strength varies from 60,000 to 65,000 pounds per square inch, and the compressive strength from 170,000 to 180,000 pounds per square inch. The melting point is at 1600 degrees F. The non-liability of Tobin bronze to give forth sparks makes it valuable for powder plates and powder-mill tools.

Average Ultimate Strength of Common Metals; Pounds per Square Inch *

Material	Tension	Compression	Shear	Modulus of Elasticity
Aluminum castings	15,000	12,000	12,000	11,000,000

Strength of Special Alloy Steel. — Chrome-vanadium steel is made by the Erie Forge Co. of the following composition: Silicon, 0.131 per cent; sulphur, 0.017 per cent; phosphorus, 0.015 per cent; manganese, 0.60 per cent; carbon, 0.32 per cent; chromium, 0.87 per cent; vanadium, 0.18 per cent.

In the annealed state a steel of this composition shows a tensile strength of 134,000 pounds per square inch, with an elastic limit of 97,000 pounds per square inch. The elongation in 2 inches is 21.1 per cent, and the reduction in area, 57.3 per cent. After having been heat treated, quenched in oil, and annealed, the steel possesses an ultimate strength of 210,000 pounds per square inch; an elastic limit of 191,500 pounds per square inch; an elongation in 2 inches of 12 per cent, and a reduction in area of 45 per cent. A forging of a connecting-rod made from this steel was twisted through an angle of 270 degrees, giving it the appearance of a cork-screw, but showed no fracture or flaw of any kind. (For strength of a number of different heat-treated alloy steels, see also the table, "Physical Properties of Heat-treated Alloy Steels.")

General Factors of Safety

Material	Steady Load	Load Varying from Zero to Maximum in one Direction	Load Varying from Zero to Maximum in both Directions	Suddenly Varying Loads and Shocks
Cast iron	6	10	15	20
Wrought iron	4	6	8	12
Steel	5	6	8	12
Wood	8	10	15	20
Brick	15	20	25	30
Stone	15	20	25	30

General Formulas for the Strength of Materials.— In the following formulas:

A = area of cross-section of material in square inches;
E = modulus of elasticity;
I = moment of inertia of section about an axis passing through the center of gravity;
I_p = polar moment of inertia of section;
M_b = maximum bending moment in inch-pounds;
M_t = moment of force tending to twist (torsional moment) in inch-pounds;
P = total stress in pounds;
y = distance from center of gravity to most remote fiber;
S = permissible working stress in pounds per square inch;
Z = section modulus for bending (moment of resistance);
Z_p = section modulus for torsion;
e = elongation or shortening in inches;
l = length in inches.

For tension and compression:

$$P = A \times S; \qquad e = \frac{Pl}{AE}.$$

For shear:

$$P = A \times S.$$

Assume permissible working stress for shear to equal about four-fifths the permissible stress in tension.

For bending:

$$M_b = \frac{SI}{y} = SZ.$$

For torsion:

$$M_t = \frac{SI_p}{y} = SZ_p.$$

The rule expressed by the formula above, that the section modulus for torsion Z_p equals the polar moment of inertia I_p, divided by the distance y from the center of gravity to the most remote fiber, holds true only for circular sections, but may also be applied with fair accuracy to sections nearly circular. For other cross-sections, the section modulus of torsion does not equal the polar moment of inertia divided by the distance from the center of gravity to the most remote fiber. For-

mulas giving the approximate section modulus for torsion for other than circular cross-sections, will be found under the head, "Polar Moment of Inertia and Polar Section Modulus." The permissible working stress for torsion may be assumed as four-fifths the permissible stress in tension.

Examples: — 1. A wrought-iron bar is to support (in tension) a load of 40,000 pounds. The load is gradually applied and then, after having reached its maximum value, gradually removed. Find the diameter of bar required.

From the accompanying tables: Ultimate strength of wrought iron = 48,000 pounds per square inch. Factor of safety to use in present case = 6. Hence, safe working stress = 48,000 ÷ 6 = 8000 pounds per square inch. Inserting the known values in formula $P = A \times S$:

$$40{,}000 = A \times 8000, \quad \text{or} \quad A = 5 \text{ square inches.}$$

The diameter of a bar, the cross-section of which is 5 square inches, is 2½ inches, approximately.

2. What would be the total elongation of the bar in the previous example under full load, if the bar were 5 feet long?

$$e = \frac{Pl}{AE} = \frac{40{,}000 \times 5 \times 12}{5 \times 27{,}000{,}000} = 0.018 \text{ inch.}$$

3. A square bar, firmly held at one end, is supporting a load of 3000 pounds at the outer free end. The length of the bar is 2½ feet. The bar is made of structural steel, and the load is steady. Find the size of bar required for safe loading.

M_b = load × lever arm in inches = 3000 × 30 = 90,000.
S = safe stress = 60,000 ÷ 5 = 12,000.
$I = s^4 \div 12$ for a square, if s = side of square.
$y = s \div 2$ in present case.

Hence:

$$M_b = \frac{SI}{y}, \quad \text{or} \quad 90{,}000 = \frac{12{,}000 \times s^4}{12 \times \frac{1}{2} s} = \frac{12{,}000\, s^3}{6}.$$

$$s^3 = 45, \quad \text{or} \quad s = 3.56 \text{ inches.}$$

4. A square bar is subjected to a steady torsional moment of 90,000 inch-pounds. The bar is made of structural steel. Find the size of bar required for safe loading.

M_t = 90,000.
$S = (60{,}000 \times \frac{4}{5}) \div 5 = 9600$.
$Z_p = \frac{2}{9} s^3$ for a square, if s = side of square.

Hence:

$$M_t = SZ_p, \quad \text{or} \quad 90{,}000 = 9600 \times \tfrac{2}{9} s^3;$$
$$s^3 = 42.2, \text{ approx.,} \quad \text{or} \quad s = 3.48 \text{ inches.}$$

Formulas for Combined Bending and Torsion. — The subject of combined bending and torsion is one that has proved more confusing to machine designers than any other phase of the strength of materials that is usually encountered by the mechanical engineer engaged in ordinary machine design. Prof. A. Lewis Jenkins, in a paper presented before the annual meeting of the American Society of Mechanical Engineers in December, 1917, thoroughly analyzes the subject and gives formulas which may be directly applied by machine designers when the bending moment, the twisting moment and the permissible working stress are known. Two formulas are given, one for the design of shafts of brittle materials and one for soft ductile materials.

Grashof Formula for Brittle Materials. — The following formula, known as the Grashof formula, may be used for the design of shafts and similar machine parts constructed of brittle materials, such as cast iron, hardened or annealed tool steel, hard bronze, and other materials having a small contraction of area when tested in tension:

$$SZ = \tfrac{3}{8} M_b + \tfrac{5}{8} \sqrt{M_b^2 + M_t^2} \qquad (1)$$

in which S = permissible or working stress in tension;
Z = rectangular (ordinary) section modulus;
M_b = bending moment to which member is subjected;
M_t = torsional moment to which member is subjected.

Formula for Soft Ductile Materials. — For the design of parts made of soft or ductile materials, such as mild (low-carbon or machine) steel, copper, soft brass and soft steel tubing, the following formulas should be used:

$$S_s Z_p = 1.3 \sqrt{M_b^2 + M_t^2} \qquad (2)$$

in which Z_p = polar section modulus,
S_s = permissible or working stress in shear,

the notation otherwise being the same as above.

The accompanying table gives values for the unit tensile and unit shearing stresses at the yield point of a number of different materials. By using a suitable factor of safety, the permissible working stresses may be obtained from this table.

Stresses at Yield Point of Different Materials

Material	Average Stress at Yield Point, Lbs. per Sq. In.	
	Tensile	Shearing
Machine steel (mild carbon steel)	47,000	30,000
Rivet steel	39,000	24,000
High-carbon steel	60,000	27,000
Nickel steel	70,000	37,000
Steel tubing	22,000	13,000

When the preceding formulas are applicable, the Guest formula, which follows, and the use of which has been advocated often, will be found unnecessary. It would perhaps be desirable if the Guest formula were not so generally recommended, because it applies only to ductile materials of circular cross-section and if used for hard or brittle materials will result in erroneous and unsuitable dimensions.

Guest Formula. — The Guest formula for parts subjected to combined bending and torsional stresses was published in 1900 by J. J. Guest as the result of experiments made by him. It is applicable to parts of circular cross-section and when such material as mild steel (machine steel) is used. The safe stress S in this formula may be assumed to be equal to the safe stress in bending. The formula is:

$$\text{Combined moment} = \sqrt{M_b^2 + M_t^2} = SZ \qquad (3)$$

This formula is used in computing the values found in the table "Diameters of Shafts for Combined Torsional and Bending Stresses."

Example: — Assume a square bar of structural steel to be subjected to combined bending and torsional moments. The bending moment is 90,000 inch-pounds and the torsional moment is 90,000 inch-pounds. Find the size of a square bar required to withstand the combined moment safely. Using formula (2) for mild steel parts subjected to combined bending and torsional stresses:

$$S_sZ_p = 1.3\sqrt{90{,}000^2 + 90{,}000^2} = 165{,}460 \text{ approximately.}$$

The safe unit-stress for shear is assumed as four-fifths or five-sixths of the permissible stress in tension; hence for structural steel the safe unit-stress equals $(60{,}000 \times \frac{4}{5} \div 5)$ or 9600 pounds per square inch; $Z_p = 0.22\ S^3$ in which S equals the side of the square; therefore

$$165{,}460 = S_sZ_p = 9600 \times 0.22\ S^3,$$

$$S^3 = 78.34 \text{ and } S = 4\tfrac{9}{32} \text{ inches.}$$

Stresses in Machine Parts

Shape of Machine Parts. — While the size of machine parts depends mainly upon the magnitude of the stresses, their shape depends to a large extent upon the manner or direction in which the load or strain is brought to bear upon them. If a part is subjected to tension only, that is, merely resists a force tending to pull it apart, then the shape is not very material, although a round rod, which is most compact and generally cheapest, is the best. Almost any other shape is satisfactory however, but it is well to avoid using thin and broad parts, as the strain might then be brought upon one edge instead of uniformly distributed over the whole area, and cause a stress in one part of the cross-section greater than that for which the material is adapted.

A machine part that is to resist compression only, should have a shape similar to that required for resisting tension, except when the proportion of its length to its diameter or thickness is such that it will be likely to buckle or bend. This will take place, in many cases, when the length exceeds five or six times the diameter and it then becomes desirable to use a hollow or cross-ribbed form of construction, with the metal as far from the axis of the piece as possible. A hollow cylindrical form is most effective, although a hollow, square or cross-ribbed form may be adopted for reasons of appearance or cheapness of production.

When a piece is designed to resist bending, it should have its greatest depth of material in the direction in which the force is applied, because the capacity of a piece to resist bending as indicated by the formula for the section modulus, increases as the square of its thickness or depth in the direction of the force, and only directly as its width. Thus, to increase the depth of a beam two or three times in the direction of the force, would increase its capacity to resist bending four or nine times; while to increase its width two or three times, would only increase its strength two or three times. The proportion of depth and width must, of course, not be carried to an extreme, as there then would be a tendency for the piece to buckle or yield sideways.

Stresses in Castings. — The stresses in castings due to shrinkage in cooling often increase, to a considerable extent, the stresses due to the load. If all parts of a casting could be made to cool equally fast, there would be little trouble from this source, but as different parts of the casting vary in thickness, the time required for cooling varies, and stressses are set up which are sometimes great enough to rupture the casting without any additional load being placed upon it. In the case of a pulley, the hub, on cooling, tends to draw the arms away from the rim. As these strains are primarily due to unequal cooling, it is evident that in order to reduce them to the lowest point, it is necessary to make the different parts of the casting as nearly uniform in thickness as possible. This, however, is not always feasible and in cases when it is not, a liberal allowance should be made for the internal stresses, by using a larger factor of safety when calculating for the external load.

Economical Sections for a Given Strength or Stiffness to Resist Bending. — When a material such as steel is used, which has practically the same properties in tension as compression, the most economical form of beam cross-section for vertical loading only, that is, a load in a single direction, is a beam of I-section, as shown in Fig. 1. For both vertical and horizontal loading, that is, for loading in two directions at right angles to each other, a beam of hollow rectangular section, as shown in Fig. 2, will require the least amount of material for a given strength and stiffness. If the load is the same in the horizontal as in the vertical direction then the cross-section will be a hollow square. For equal loading in any direction, a hollow circular section, Fig. 3, should be used.

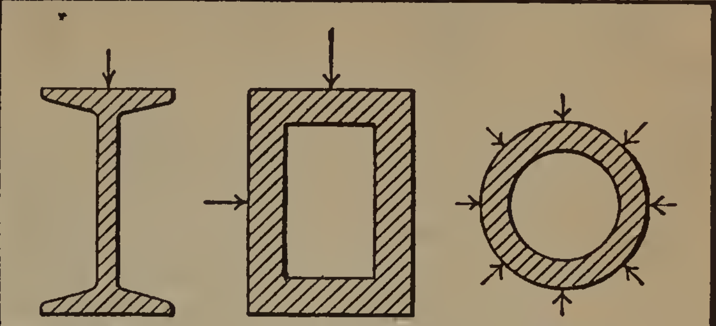

Fig. 1 Fig. 2 Fig. 3

Stresses Due to Changes of Temperature. — If a bar of metal is confined in a space so that it is prevented from expanding or contracting, stresses will be induced in it if it is subjected to temperature changes. These stresses are termed "temperature stresses," and their magnitude is measured by the amount of compression or elongation. If T = change in temperature in degrees F.; S = stress produced by the temperature change, per square inch; C = coefficient of linear expansion; and E = modulus of elasticity, then: $S = C \times T \times E$.

The values of the coefficient of linear expansion for one degree F. equals 0.0000074, for high-carbon steel; 0.0000065, for mild (machine) steel; 0.0000062, for cast iron; and 0.0000068, for wrought iron.

Bending Stresses Combined with Direct Tension or Compression. — In U-shaped machine parts, such as, for example, punch or shear frames, the metal in the back of the frame resists a uniformly distributed tensile stress, due to the pressure between the jaws, and also a stress due to the bending moment set up by the same pressure. The maximum tensile stress, therefore, is composed of the sum of this uniformly distributed stress and the stress due to the bending moment. If the pressure on a machine part is in such a direction that the stresses induced are partly compression and partly bending stresses, then the stress due to direct compression is added to the compressive stress due to bending, in order to find the total compressive stress to which the machine part is subjected.

Shear Stresses Combined with Tension or Compression Stresses. — The rather complicated calculations necessary in cases where shear stresses are combined with tension or compression stresses may be avoided by using the accompanying table which gives factors by means of which the maximum combined unit shear and the maximum combined unit tension or compression may be determined, when the forces causing shear and tension or compression are known. For example, assume that the unit shear S, as produced by the force causing shear alone, is 9000 pounds per square inch, and that the unit tension or compression T, produced by the force that causes tension or compression only, is 12,000 pounds per square inch. Then the ratio $S \div T = 0.75$, and from the table it is then found that the tension (or compression) factor $x = 1.401$ for this ratio of S to T. This means that in this case the maximum combined tension will be 1.401 times what it would have been if there had been no shear. The shear factor y is 1.20, indicating that the maximum combined shear stress is 1.20 times what it would have been if there had been no tension or compression stresses. If the separate unit stresses are known, therefore, the total combined stresses may be quickly determined by this table.

Shear Stresses Combined with Tension or Compression Stresses

Ratio $\frac{S}{T}$	Tension Factor x	Shear Factor y	Ratio $\frac{S}{T}$	Tension Factor x	Shear Factor y
0.05	1.002	10.05	0.80	1.44	1.18

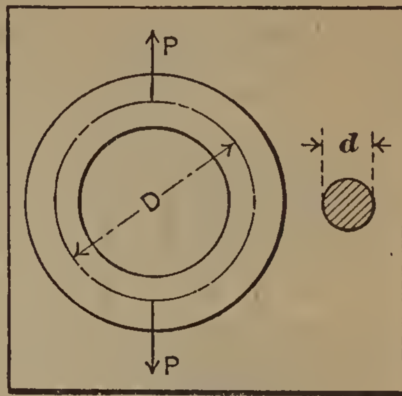
Combined Torsion and Compression. — Propeller shafts of steamers and vertical shafts carrying considerable weight, are subjected to combined torsion and compression. Let P_1 = maximum resultant compressive stress; P_2 = maximum resultant shearing stress; C = the compressive stress due to the thrust; S = the shearing stress due to the twisting moment. Then,

$$P_1 = \tfrac{1}{2}\left(C + \sqrt{C^2 + 4S^2}\right); \qquad P_2 = \tfrac{1}{2}\sqrt{C^2 + 4S^2}$$

Stresses in a Loaded Ring. — The load that may be safely carried by a ring loaded as indicated by the accompanying engraving is found from the formula:

$$P = \frac{2\,S\pi I}{Dy}$$



in which P = load on ring, in pounds; D = mean diameter of ring, in inches; S = allowable working stress in pounds per square inch; I = moment of inertia of section; y = distance from the center of gravity of the section to the most remote fiber, in inches.

For a ring of circular section, where d equals the diameter of the bar from which the ring is made:

$$P = 0.617\,S\frac{d^3}{D} \qquad S = 1.621\,P\frac{D}{d^3}$$

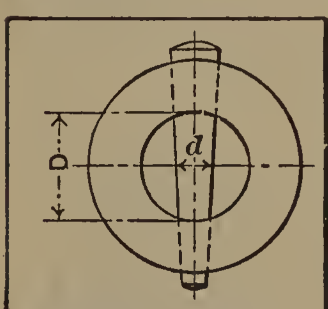
These formulas are especially applicable to loaded rings in which the diameter d is small in proportion to the mean diameter D, because it is only in such cases that the bending action becomes important. For loaded rings having an internal diameter small in proportion to the diameter of the stock, as in the case of eyebolts, the formulas would not apply, because then the metal is stressed largely in direct tension, and the formulas would give excessive dimensions.

Strength of Taper Pins. — The mean diameter of taper pin required to safely transmit a known turning moment, may be found from the formulas:

$$d = 1.13\sqrt{\frac{PR}{DS}} \quad . \quad . \quad . \quad (1), \quad \text{and} \quad d = 283\sqrt{\frac{\text{H.P.}}{NDS}} \quad . \quad . \quad . \quad (2)$$

in which formulas PR = turning moment in inch-pounds; S = safe unit stress = 6000 pounds per square inch; H.P. = horsepower transmitted; N = number of revolutions per minute; and d and D denote dimensions shown in the engraving.

Examples: — A lever secured to a 2-inch round shaft by a steel tapered pin (dimension d = 3/8 inch) has a pull of 50 pounds at a 30-inch radius from shaft center. Find S, the unit working stress on the pin. By transposing Formula (1):



$$S = \frac{1.27\,PR}{Dd^2} = \frac{1.27 \times 50 \times 30}{2 \times (\frac{3}{8})^2} = 6770$$

pounds per square inch (nearly), which is a safe unit working stress for machine steel in shear.

Let P = 50 pounds, R = 30 inches, D = 2 inches, and S = 6000 pounds unit working stress. Using Formula (1) to find d:

$$d = 1.13\sqrt{\frac{PR}{DS}} = 1.13\sqrt{\frac{50 \times 30}{2 \times 6000}} = 1.13\sqrt{\frac{1}{8}} = 0.4 \text{ inch.}$$

Tables of Moments of Inertia, Section Moduli, etc. — On the following pages are given tables of the moments of inertia and other properties of forty-two different cross-sections of such outlines as are most frequently met with in structural steel shapes or in cast-iron designs. The tables give the area of the section and the distance y from the neutral axis to the extreme fiber, in each case. In some cases, where the formulas for the section modulus and radius of gyration are very lengthy, the formula for the section modulus, for example, has been simply given as $\frac{I}{y}$. The radius of gyration is sometimes given as $\sqrt{\frac{I}{A}}$, when the complete formula would be too long to put into the space available.

Moments of Inertia, Section Moduli, etc., of Sections

Section Modulus, Area, etc., of Sections for Punch and Shear Frames.— Machine frames cannot be standardized so as to permit tables of section modulus, area, etc., of the sections to be made up in the same way as for standard structural steel sections, but it is possible to arrange a table for punch and shear frames so as to simplify the work of selecting proper sections. A table of these quantities is, therefore, given. To illustrate the use of the table, take as an example the punch frame shown diagrammatically in Fig. 1. The distance from the center line of the punch to the back of the gap is 24 inches. Assume that the maximum pressure *P*, tending to force the jaws apart, is that due to punching a 1-inch circular hole in soft steel plate 1 inch thick, or say about 157,000 pounds. Consider the section at *TX*. The action of *P* is such as to produce a tensile stress on the section to the left of the neutral axis *N*, with a compressive stress to the right of *N*, both due to

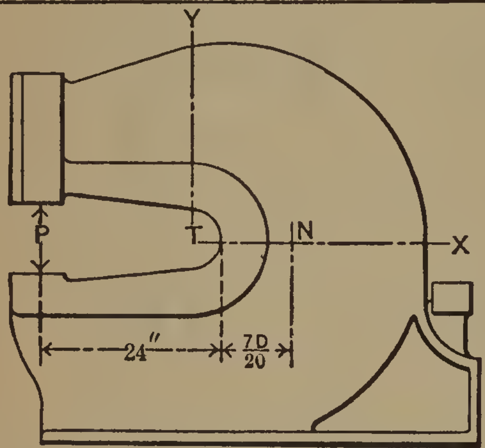

Fig. 1

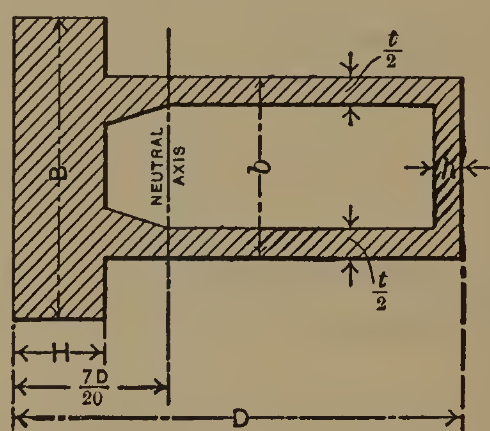

Fig. 2

flexure; and, besides, there is a tensile stress distributed uniformly over the section. It is usually sufficient to determine the maximum tensile stress to the left of *N*.

Maximum tensile stress = flexure tensile stress + uniformly distributed tensile stress.

$$\text{Flexure tensile stress} = \frac{\text{Moment of } P \text{ about } N}{\text{Tensile section modulus of section } TX}$$

$$\text{Uniformly distributed tensile stress} = \frac{P}{\text{Area of section } TX}$$

Assume that *D*, in Fig. 2, is about 30 inches. Then $\frac{7\,D}{20} = 10\frac{1}{2}$ inches. If 3000 pounds per square inch is the allowable fiber stress, and the stress due to flexure only is considered, the required section modulus for tension would be:

$$\frac{157{,}000 \times (24 + 10\frac{1}{2})}{3000} = 1800, \text{ about.}$$

As no allowance has been made for the additional tensile stress uniformly distributed over the section, a section must be selected the section modulus of which is somewhat greater than 1800, say about 2500.

The table of "Properties of Sections for Punch and Shear Frames" gives a great variety of shapes and proportions, the only dimensions common to all being the depth of section, *D*, and the distance of the neutral axis from the extreme tension fiber. This location of the neutral axis represents average practice and insures an economical distribution of metal. Generous fillets and rounded corners should, of course, be used on the actual section.

Suppose that a deep narrow section is desired, similar to that in Fig. 2, in which the dimensions are as follows: $D = 10$ inches; $B = 7$ inches; $b = 4$ inches; $H = 1.98$ inch; $\frac{1}{2}t = h = \frac{5}{8}$ inch; F (area) = 26.3 square inches; and Z_t (section modulus for tension) = 78.6. This section, taken from the table, is not, of course, large enough, but a similar one which is large enough may be easily found as follows:

If two sections A and B are similar in all respects, then

$$\frac{\text{Area of } A}{\text{Area of } B} = \frac{(\text{Any dimension of } A)^2}{(\text{Corresponding dimension of } B)^2};$$

and

$$\frac{\text{Section modulus of } A}{\text{Section modulus of } B} = \frac{(\text{Any dimension of } A)^3}{(\text{Corresponding dimension of } B)^3};$$

$$\frac{\text{Required section modulus}}{\text{Modulus of section from the table}} = \frac{(\text{Required } D)^3}{(D \text{ of section from the table})^3}$$

Hence, $\frac{2500}{78.6} = \frac{(\text{Required } D)^3}{(10)^3}$. This last equation solved for D gives $D = 31.7$ inches, nearly. As the large section will be exactly similar to the small one, the area of the large section is found from the equation:

$$\frac{\text{Area of required section}}{26.3} = \frac{(31.7)^2}{(10)^2}$$

and area = 264 square inches, about.

The neutral axis will be $\frac{7}{20} \times 31.7$, or 11.1 inches from the extreme tension fiber.

This trial section may now be tested for the maximum stress on it.

Flexure tensile stress $= \frac{157{,}000 \times (24 + 11.1)}{2500} = 2200$ pounds per square inch, about.

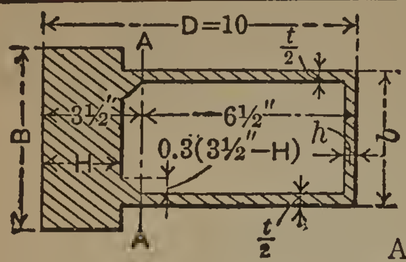
Uniformly distributed tensile stress $= \frac{157{,}000}{264} = 600$ pounds per square inch, about.

The total tensile stress is, therefore, 2800 pounds per square inch.

If this result had not been near enough to the 3000 pounds per square inch assumed, another section could have been selected and worked out in the same way to get a closer result. The depth D of the required section being 31.7 inches as compared with 10 inches of the similar section given in the table, each of the dimensions of the required section will be 3.17 times the corresponding one given in the table. Hence $D = 31.7$, say 32 inches; $B = 22.2$, say 22 inches; $b = 12.7$, say 13 inches; $H = 6.3$, say $6\frac{1}{2}$ inches, $\frac{1}{2}t = h = 1.98$, say 2 inches. The webs thicken gradually from the neutral axis to the tension flange so as to avoid too sudden a change in the section. For selecting the section at TY, Fig. 1, the procedure would be the same except that there would be no uniformly distributed stress to be added as in the case of section TX.

The method here given for determining the stress on the section TX is the one which is generally used in calculating the strength of shear frames and other designs of similar type. It is correct for straight beams, and until recently it was considered approximately correct for curved beams, but investigations by Bach and others indicate that the maximum stresses in curved beams are very much greater than found by the methods generally used. A quick and accurate way of applying the new theory has, however, not yet been devised, and for this reason the only possible way is to use the method outlined and provide an ample factor of safety. This is a safe course, because cast-iron punch frames, the sections of which have been determined by these methods, have stood up under their loads for years.

Properties of Sections for Punch and Shear Frames



Z_c = Section Modulus for Compression;
Z_t = Section Modulus for Tension;
F = Area of Section;
I = Moment of Inertia about Gravity Axis $A-A$.

Length of Angles Bent to Circular Shape. — When it is required to calculate the length of an angle-iron used either inside or outside of a tank or smokestack, the following method and table of constants may be used: Assume, for example, that a stand-pipe, 20 feet inside diameter, is provided with a 3 by 3 by 3/8 inch angle-iron on the inside at the top. The circumference of a circle 20 feet in diameter is 754 inches. From the table of constants, find the constant for a 3 by 3 by 3/8 inch angle-iron, which is 4.319. The length of the angle then is 754 − 4.319 = 749.681 inches. Should the angle be on the outside, add the constant instead of subtracting it; thus, 754 + 4.319 = 758.319 inches.

Table of Constants Used for Calculating Length of Angles Bent to Circular Shape

Size of Angle	Constant	Size of Angle	Constant
1/4 × 2 × 2	2.879	1/2 × 3 1/2 × 3 1/2	5.235
5/16 × 2 × 2	3.076	3/8 × 4 × 4	5.366
3/8 × 2 × 2	3.272	1/2 × 4 × 4	5.758
1/4 × 2 1/2 × 2 1/2	3.403	3/8 × 5 × 5	6.414
5/16 × 2 1/2 × 2 1/2	3.600	1/2 × 5 × 5	6.804
3/8 × 2 1/2 × 2 1/2	3.796	3/8 × 6 × 6	7.461
1/2 × 2 1/2 × 2 1/2	4.188	1/2 × 6 × 6	7.854
1/4 × 3 × 3	3.926	3/4 × 6 × 6	8.639
5/16 × 3 × 3	4.123	1/2 × 8 × 8	9.949
3/8 × 3 × 3	4.319	3/4 × 8 × 8	10.734
1/2 × 3 × 3	4.711	1 × 8 × 8	11.520
3/8 × 3 1/2 × 3 1/2	4.843	....	......

Moment of Inertia of Built-up Sections. — The usual method of calculating the moment of inertia of a built-up section involves the calculations of the moment of inertia for each element of the section about its own neutral axis, and the transferring of this moment of inertia to the previously found neutral axis of the whole built-up section. A much simpler method that can be used in the case of any section which can be divided into rectangular elements bounded by lines parallel

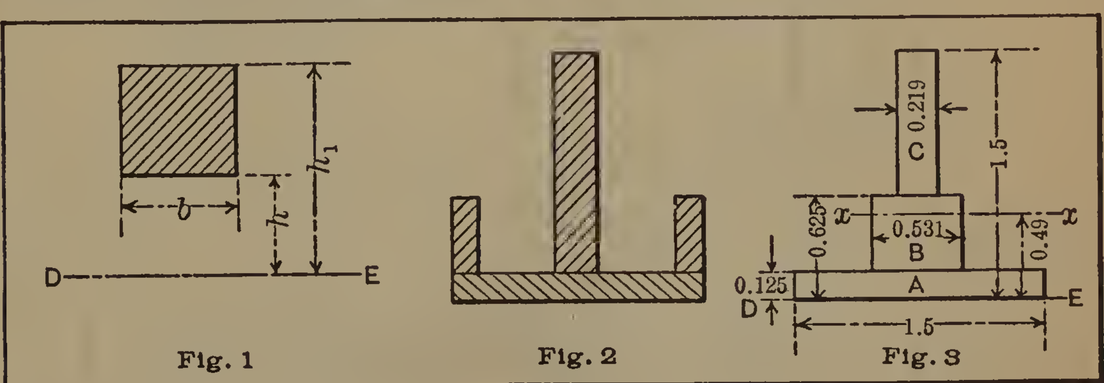

Fig. 1 Fig. 2 Fig. 3

and perpendicular to the neutral axis, is the so-called tabular method based upon the formula: $I = \frac{b\,(h_1^3 - h^3)}{3}$ in which I = the moment of inertia about axis DE, Fig. 1, and b, h and h_1 are dimensions as given in the same illustration.

The method may be illustrated by applying it to the section shown in Fig. 2, and for simplicity of calculation shown "massed" in Fig. 3. The calculation may then be tabulated as shown in the accompanying table. The distance from the axis *DE* to the neutral axis *xx* (which will be designated as *d*) is found by dividing the sum of the geometrical moments by the area. The moment of inertia about the neutral axis is then found in the usual way by subtracting the area multiplied by d^2 from the moment of inertia about the axis *DE*.

Tabulated Calculation of Moment of Inertia

Section	Breadth b	Height h_1	Area $b\,(h_1 - h)$	h_1^2	Moment $\dfrac{b\,(h_1^2 - h^2)}{2}$	h_1^3	I about axis DE $\dfrac{b\,(h_1^3 - h^3)}{3}$
A	1.500	0.125	0.187	0.016	0.012	0.002	0.001
B	0.531	0.625	0.266	0.391	0.100	0.244	0.043
C	0.219	1.500	0.191	2.250	0.203	3.375	0.228
			$A = 0.644$		$M = 0.315$		$I_{DE} = 0.272$

Distance d from DE to $xx = \dfrac{M}{A} = \dfrac{0.315}{0.644} = 0.49.$

Moment of inertia of whole section with reference to its neutral axis: $I_n = I_{DE} - Ad^2 = 0.272 - 0.644 \times 0.49^2 = 0.117.$

Sections for Crane and Telpher Runways. — In the design of crane, telpher and similar runways, suitable provision should be made for the lateral strength. The three types of section most commonly used for the purposes mentioned consist of: 1. An I-beam for vertical strength with a channel riveted to the compression flange for lateral stiffness. 2. The same construction, with the addition of a smaller

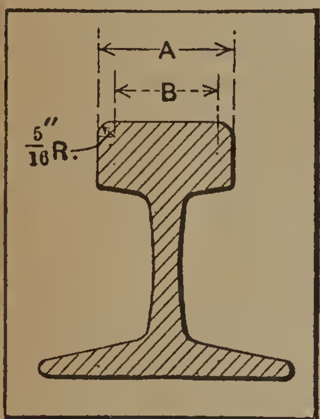
channel to the tension flange to increase the vertical strength. 3. Two I-beams side by side, with a cover plate on the top flanges only. An illustration of each of these three types is shown in the tables of "Sections for Crane and Telpher Runways," where the section modulus, moment of inertia and other properties of the three types of built-up sections are given.

Size of Rail Necessary to Carry a Given Load. — The following formulas may be employed for determining the size of rail and wheel suitable for carrying a given load. Let, A = the width of the head of the rail in inches; B = width of the tread of the rail in inches; C = the wheel-load in pounds; D = the diameter of the wheel in inches.



Then the width of the tread of the rail in inches is found from the formula:

$$B = \frac{C}{1250\,D} \tag{1}$$

The width A of the head equals $B + \frac{5}{8}$ inch. The diameter D of the smallest track wheel that will safely carry the load is found from the formula:

$$D = \frac{C}{A \times K} \tag{2}$$

in which K = 600 to 800 for steel castings; K = 300 to 400 for cast iron.

As an example, assume that the wheel-load in a given case is 10,000 pounds; the diameter of the wheel is 20 inches; and the material steel casting. Determine the size of rail necessary to carry this load. From Formula (1):

$$B = \frac{10{,}000}{1250 \times 20} = 0.4 \text{ inch.}$$

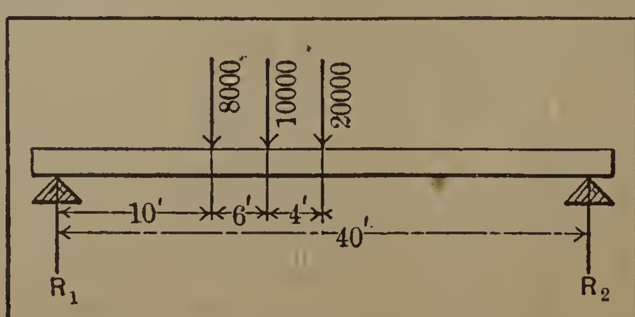
Hence the width of the rail required equals $0.4 + \frac{5}{8}$ inch = 1.025 inch. Determine also whether a wheel 20 inches in diameter is large enough to safely carry the load. From Formula (2):

$$D = \frac{10{,}000}{1.025 \times 600} = 16\tfrac{1}{4} \text{ inches.}$$

This is the smallest diameter of track wheel that will safely carry the load; hence a 20-inch wheel is ample.

BEAMS

Reaction at the Supports. — When a beam is loaded by vertical loads or forces, the sum of the reactions at the supports equals the sum of the loads. In a simple beam, when the loads are symmetrically placed with reference to the supports, or when the load is uniformly distributed, the reaction at each end will equal one-half of the sum of the loads. When the loads are not symmetrically placed, the reaction at each support may be ascertained from the fact that the algebraic sum of the moments must equal zero. In the accompanying illustration, if moments are taken about the support to the left, then:



$$R_2 \times 40 - 8000 \times 10 - 10{,}000 \times 16 - 20{,}000 \times 20 = 0;$$
$$R_2 = 16{,}000 \text{ pounds.}$$

Moments taken about the support at the right will, in the same way, give

$$R_1 = 22{,}000 \text{ pounds.}$$

The sum of the reactions equals 38,000 pounds, which is also the sum of the loads. If part of the load is uniformly distributed over the beam, this part is first equally divided between the two supports, or the uniform load may be considered as concentrated at its center of gravity.

Stresses and Deflections in Beams. — On the following pages is given an extensive table of formulas for stresses and deflections in beams, shafts, etc. It is assumed that all the dimensions are in inches, all loads in pounds, and all stresses in pounds per square inch. In the tables:

E = modulus of elasticity of the material;
I = moment of inertia of the cross-section of the beam;
Z = section modulus of the cross-section of the beam = $I \div$ distance from neutral axis to extreme fiber;
W = load on beam;
s = stress in extreme fiber, or maximum stress in the cross-section considered, due to load W. A positive value of s denotes tension in the upper fibers and compression in the lower ones (as in a cantilever). A negative value of s denotes the reverse (as in a beam supported at the ends). The greatest safe load is that value of W which causes a maximum stress equal to, but not exceeding, the greatest safe value of s;
y = deflection measured from the position occupied if the load causing the deflection were removed. A positive value of y denotes deflection below this position; a negative value, deflection upward;
u, v, w, x = variable distances along the beam from a given support to any point.

If there are several kinds of loads, as, for instance, a uniform load and a load at any point, or separate loads at different points, the total stress and the total deflection at any point is found by adding together the various stresses or deflections at the point considered due to each load acting by itself. If the stress or deflection due to any one of the loads is negative, it must be subtracted instead of added.

Remarks Relative to the Use of the Tables. — In the diagrammatical illustrations of the beams and their loading, the values indicated near, but below, the supports are the "reactions" or upward forces at the supports. For Cases 1 to 12, inclusive, the reactions, as well as the formulas for the stresses, are the same whether the beam is of constant or variable cross-section. For the other cases, the reactions and the stresses given are for constant cross-section beams only.

The bending moment at any point in inch-pounds is $s \times Z$ and can be found by omitting the divisor Z in the formula for the stress given in the tables. A positive value of the bending moment denotes tension in the upper fibers and compression in the lower ones. A negative value denotes the reverse. The value of W corresponding to a given stress is found by transposition of the formula. For example, in Case 1, the stress at the critical point is $s = -Wl \div 8Z$. From this we find $W = -8Zs \div l$. Of course, the negative sign of W may be ignored.

The deflections given in the tables apply only to cases where the cross-section of the beam is constant for its entire length.

Stresses and Deflections in Beams

Type of Beam	Stresses: General Formula for Stress at any Point	Stresses: Stresses at Critical Points
Case 1. — Supported at Both Ends, Uniform Load TOTAL LOAD W 	$s = -\dfrac{W}{2Zl}x(l-x)$	Stress at center, $-\dfrac{Wl}{8Z}$. If cross-section is constant, this is the maximum stress.
Case 2. — Supported at Both Ends, Load at Center 	Between each support and load, $s = -\dfrac{Wx}{2Z}$	Stress at center, $-\dfrac{Wl}{4Z}$ If cross-section is constant, this is the maximum stress.
Case 3. — Supported at Both Ends, Load at any Point  $a+b=l$	For segment of length a, $s = -\dfrac{Wbx}{Zl}$ For segment of length b, $s = -\dfrac{Wav}{Zl}$	Stress at load, $-\dfrac{Wab}{Zl}$ If cross-section is constant, this is the maximum stress.
Case 4. — Supported at Both Ends, Two Symmetrical Loads 	Between each support and adjacent load, $s = -\dfrac{Wx}{Z}$ Between loads, $s = -\dfrac{Wa}{Z}$	Stress at each load, and at all points between, $-\dfrac{Wa}{Z}$
Case 5. — Both Ends Overhanging Supports Symmetrically, Uniform Load TOTAL LOAD W  $L=l+2c$	Between each support and adjacent end, $s = \dfrac{W}{2ZL}(c-u)^2$ Between supports, $s = \dfrac{W}{2ZL}[c^2 - x(l-x)]$	Stress at each support, $\dfrac{Wc^2}{2ZL}$ Stress at center, $\dfrac{W}{2ZL}(c^2 - \frac{1}{4}l^2)$ If cross-section is constant, the greater of these is the maximum stress. If l is greater than $2c$, the stress is zero at points $\sqrt{\frac{1}{4}l^2 - c^2}$ on both sides of the center. If cross-section is constant and if $l = 2.828c$, the stresses at supports and center are equal and opposite, and are $\pm\dfrac{WL}{46.62Z}$

Stresses and Deflections in Beams

Deflections	
General Formula for Deflection at any Point	Deflections at Critical Points
$y = \frac{Wx(l-x)}{24\,EIl}[l^2 + x(l-x)]$	Maximum deflection, at center, $\frac{5}{384}\frac{Wl^3}{EI}$
Between each support and load, $y = \frac{Wx}{48\,EI}(3\,l^2 - 4\,x^2)$	Maximum deflection, at load, $\frac{Wl^3}{48\,EI}$
For segment of length a, $y = \frac{Wbx}{6\,EIl}(l^2 - x^2 - b^2)$ For segment of length b, $y = \frac{Wav}{6\,EIl}(l^2 - v^2 - a^2)$	Deflection at load, $\frac{Wa^2b^2}{3\,EIl}$ Let a be the length of the shorter segment and b of the longer one. The maximum deflection is in the longer segment, at $v = b\sqrt{\frac{1}{3} + \frac{2\,a}{3\,b}} = v_1$, and is $\frac{Wav_1^3}{3\,EIl}$
Between each support and adjacent load. $y = \frac{Wx}{6\,EI}[3\,a(l-a) - x^2]$ Between loads, $y = \frac{Wa}{6\,EI}[3\,v(l-v) - a^2]$	Maximum deflection at center, $\frac{Wa}{24\,EI}(3\,l^2 - 4\,a^2)$ Deflection at loads $\frac{Wa^2}{6\,EI}(3\,l - 4\,a)$
Between each support and adjacent end, $y = \frac{Wu}{24\,EIL}[6\,c^2(l+u) - u^2(4\,c-u) - l^3]$ Between supports, $y = \frac{Wx(l-x)}{24\,EIL}[x(l-x) + l^2 - 6\,c^2]$	Deflection at ends, $\frac{Wc}{24\,EIL}[3\,c^2(c+2\,l) - l^3]$ Deflection at center, $\frac{Wl^2}{384\,EIL}(5\,l^2 - 24c^2)$ If l is between $2\,c$ and $2.449\,c$, there are maximum upward deflections at points $\sqrt{3\,(\frac{1}{4}\,l^2 - c^2)}$ on both sides of the center, which are, $-\frac{W}{96\,EIL}(6\,c^2 - l^2)^2$

Stresses and Deflections in Beams

Type of Beam	Stresses: General Formula for Stress at any Point	Stresses: Stresses at Critical Points
Case 6. — Both Ends Overhanging Supports Unsymmetrically, Uniform Load TOTAL LOAD W 	For overhanging end of length c, $s = \frac{W}{2ZL}(c-u)^2$ Between supports, $s = \frac{W}{2ZL}\left\{c^2\left(\frac{l-x}{l}\right) + d^2\frac{x}{l} - x(l-x)\right\}$ For overhanging end of length d, $s = \frac{W}{2ZL}(d-w)^2$	Stress at support next end of length c, $\frac{Wc^2}{2ZL}$ Critical stress between supports is at $x = \frac{l^2+c^2-d^2}{2l} = x_1$ and is $\frac{W}{2ZL}(c^2 - x_1^2)$ Stress at support next end of length d, $\frac{Wd^2}{2ZL}$ If cross-section is constant, the greatest of these three is the maximum stress. If $x_1 > c$, the stress is zero at points $\sqrt{x_1^2-c^2}$ on both sides of $x = x_1$.
Case 7. — Both Ends Overhanging Supports, Load at any Point Between 	Between supports: For segment of length a, $s = -\frac{Wbx}{Zl}$ For segment of length b, $s = -\frac{Wav}{Zl}$ Beyond supports $s = 0$.	Stress at load, $-\frac{Wab}{Zl}$ If cross-section is constant, this is the maximum stress.
Case 8. — Both Ends Overhanging Supports, Single Overhanging Load 	Between load and adjacent support, $s = \frac{W}{Z}(c-u)$ Between supports, $s = \frac{Wc}{Zl}(l-x)$ Between unloaded end and adjacent support, $s = 0$.	Stress at support adjacent to load, $\frac{Wc}{Z}$ If cross-section is constant, this is the maximum stress. Stress is zero at other support.
Case 9. — Both Ends Overhanging Supports, Symmetrical Overhanging Loads 	Between each load and adjacent support, $s = \frac{W}{Z}(c-u)$ Between supports, $s = \frac{Wc}{Z}$	Stress at supports and at all points between, $\frac{Wc}{Z}$ If cross-section is constant, this is the maximum stress.

Stresses and Deflections in Beams

Deflections	
General Formula for Deflections at any Point	Deflections at Critical Points
For overhanging end of length c, $y=\frac{Wu}{24\,EIL}[2\,l\,(d^2+2\,c^2)+6\,c^2u-u^2\,(4\,c-u)-l^3]$ Between supports, $y=\frac{Wx\,(l-x)}{24\,EIL}\left\{x\,(l-x)+l^2-2\,(d^2+c^2)-\frac{2}{l}[d^2x+c^2\,(l-x)]\right\}$ For overhanging end of length d, $y=\frac{Ww}{24\,EIL}[2\,l\,(c^2+2\,d^2)+6\,d^2w-w^2\,(4\,d-w)-l^3]$	Deflection at end c, $\frac{Wc}{24\,EIL}[2\,l\,(d^2+2\,c^2)+3\,c^3-l^3]$ Deflection at end d, $\frac{Wd}{24\,EIL}[2\,l\,(c^2+2\,d^2)+3\,d^3-l^3]$ This case is so complicated that convenient general expressions for the critical deflections between supports cannot be obtained.
Between supports, same as Case 3. For overhanging end of length c, $y=-\frac{Wabu}{6\,EIl}(l+b)$ For overhanging end of length d, $y=-\frac{Wabw}{6\,EIl}(l+a)$	Between supports, same as Case 3. Deflection at end c, $-\frac{Wabc}{6\,EIl}(l+b)$ Deflection at end d, $-\frac{Wabd}{6\,EIl}(l+a)$
Between load and adjacent support, $y=\frac{Wu}{6\,EI}(3\,cu-u^2+2\,cl)$ Between supports, $y=-\frac{Wcx}{6\,EIl}(l-x)(2\,l-x)$ Between unloaded end and adjacent support, $y=\frac{Wclw}{6\,EI}$	Deflection at load, $\frac{Wc^2}{3\,EI}(c+l)$ Maximum upward deflection is at $x=0.42265\,l$, and is $-\frac{Wcl^2}{15.55\,EI}$ Deflection at unloaded end, $\frac{Wcld}{6\,EI}$
Between each load and adjacent support, $y=\frac{Wu}{6\,EI}[3\,c\,(l+u)-u^2]$ Between supports, $y=-\frac{Wcx}{2\,EI}(l-x)$	Deflections at loads, $\frac{Wc^2}{6\,EI}(2\,c+3\,l)$ Deflection at center, $-\frac{Wcl^2}{8\,EI}$

The above expressions involve the usual approximations of the theory of flexure, and hold only for small deflections. Exact expressions for deflections of any magnitude are as follows:

Between supports the curve is a circle of radius $r=\frac{EI}{Wc}$; $y=\sqrt{r^2-\frac{1}{4}l^2}-\sqrt{r^2-(\frac{1}{2}l-x)^2}$

Deflection at center, $\sqrt{r^2-\frac{1}{4}l^2}-r$

Stresses and Deflections in Beams

Type of Beam	Stresses: General Formula for Stress at any Point	Stresses: Stresses at Critical Points
Case 19. — Fixed at Both Ends, Load at Center 	Between each end and load, $s = \frac{W}{2Z}(\frac{1}{4}l - x)$	Stress at ends $\frac{Wl}{8Z}$; at load $-\frac{Wl}{8Z}$ These are the maximum stresses and are equal and opposite. Stress is zero at $x = \frac{1}{4}l$
Case 20. — Fixed at Both Ends, Load at any Point 	For segment of length a, $s = \frac{Wb^2}{Zl^3}[al - x(l+2a)]$ For segment of length b, $s = \frac{Wa^2}{Zl^3}[bl - v(l+2b)]$	Stress at end next segment of length a, $\frac{Wab^2}{Zl^2}$ Stress at end next segment of length b, $\frac{Wa^2b}{Zl^2}$ Maximum stress is at end next shorter segment. Stress is zero for $x = \frac{al}{l+2a}$ and $v = \frac{bl}{l+2b}$ Greatest negative stress, at load, $-\frac{2Wa^2b^2}{Zl^3}$
Case 21. — Continuous Beam, with Two Equal Spans, Uniform Load TOTAL LOAD ON EACH SPAN, W 	$s = \frac{W(l-x)}{2Zl}(\frac{1}{4}l - x)$	Maximum stress at point A, $\frac{Wl}{8Z}$ Stress is zero at $x = \frac{1}{4}l$. Greatest negative stress is at $x = \frac{5}{8}$ and is, $-\frac{9}{128}\frac{Wl}{Z}$
Case 22. — Continuous Beam, with Two Unequal Spans, Unequal, Uniform Loads TOTAL LOAD W_1 TOTAL LOAD W_2  $\frac{l_1W_1(3l_1+4l_2)-W_2l_2^2}{8l_1(l_1+l_2)}$ $\frac{l_2W_2(3l_2+4l_1)-W_1l_1^2}{8l_2(l_1+l_2)}$ $\left(\frac{W_1+W_2}{2}\right)+\frac{1}{8}\left(\frac{W_1l_1}{l_2}+\frac{W_2l_2}{l_1}\right)$	Between R_1 and R, $s = \frac{l_1-x}{Z}\left\{\frac{(l_1-x)W_1}{2l_1} - r_1\right\}$ Between R_2 and R, $s = \frac{l_2-u}{Z}\left\{\frac{(l_2-u)W_2}{2l_2} - r_2\right\}$	Stress at support R, $\frac{W_1l_1^2 + W_2l_2^2}{8Z(l_1+l_2)}$ Greatest stress in the first span is at $x = \frac{l_1}{W_1}(W_1 - r_1)$, and is, $-\frac{r_1^2l_1}{2ZW_1}$ Greatest stress in the second span is at $u = \frac{l_2}{W_2}(W_2 - r_2)$, and is, $-\frac{r_2^2l_2}{2ZW_2}$

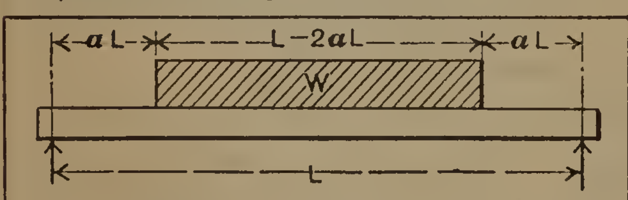
Stresses and Deflections in Beams

Deflections	
General Formula for Deflections at any Point	Deflections at Critical Points
$y = \frac{Wx^2}{48\,EI}(3\,l - 4\,x)$	Maximum deflection, at load, $\frac{Wl^3}{192\,EI}$
For segment of length a, $y = \frac{Wx^2b^2}{6\,EIl^3}[2\,a\,(l - x) + l\,(a - x)]$ For segment of length b, $v = \frac{Wv^2a^2}{6\,EIl^3}[2\,b\,(l - v) + l\,(b - v)]$	Deflection at load, $\frac{Wa^3b^3}{3\,EIl^3}$ Let b be the length of the longer segment and a of the shorter one. The maximum deflection is in the longer segment, at $v = \frac{2\,bl}{l + 2\,b}$, and is $\frac{2\,Wa^2b^3}{3\,EI\,(l + 2\,b)^2}$
$y = \frac{Wx^2\,(l - x)}{48\,EIl}(3\,l - 2\,x)$	Maximum deflection is at $x = 0.5785\,l$, and is $\frac{Wl^3}{185\,EI}$ Deflection at center of span, $\frac{Wl^3}{192\,EI}$ Deflection at point of greatest negative stress, at $x = \frac{5}{8}\,l$ is $\frac{Wl^3}{187\,EI}$
Between R_1 and R, $y = \frac{x\,(l_1 - x)}{24\,EI}\left\{(2\,l_1 - x)\,(4\,r_1 - W_1) - \frac{W_1\,(l_1 - x)^2}{l_1}\right\}$ Between R_2 and R, $y = \frac{u\,(l_2 - u)}{24\,EI}\left\{(2\,l_2 - u)\,(4\,r_2 - W_2) - \frac{W_2\,(l_2 - u)^2}{l_2}\right\}$	This case is so complicated that convenient general expressions for the critical deflections cannot be obtained.

Stresses and Deflections in Beams

Type of Beam	Stresses: General Formula for Stress at any Point	Stresses: Stresses at Critical Points
Case 23. — Continuous Beam, with Two Equal Spans, Equal Loads at Center of Each 	Between point A and load, $s = \frac{W}{16Z}(3l - 11x)$ Between point B and load, $s = -\frac{5}{16}\frac{Wv}{Z}$	Maximum stress at point A, $\frac{3}{16}\frac{Wl}{Z}$ Stress is zero at $x = \frac{3}{11}l$ Greatest negative stress at center of span, $-\frac{5}{32}\frac{Wl}{Z}$
Case 24. — Continuous Beam, with Two Unequal Spans, Unequal Loads at any Point of Each $m = \frac{1}{2(l_1+l_2)}\left(\frac{W_1a_1b_1}{l_1}(l_1+a_1) + \frac{W_2a_2b_2}{l_2}(l_2+a_2)\right)$  $\frac{W_1b_1 - m}{l_1} = r_1$ $\quad \frac{W_1a_1+m}{l_1} + \frac{W_2a_2+m}{l_2} = r$ $\quad \frac{W_2b_2-m}{l_2} = r_2$	Between R_1 and W_1, $s = -\frac{wr_1}{Z}$ Between R and W_1, $s = \frac{1}{l_1Z}[m(l_1-u) - W_1a_1u]$ Between R and W_2, $s = \frac{1}{l_2Z}[m(l_2-x) - W_2a_2x]$ Between R_2 and W_2, $s = -\frac{vr_2}{Z}$	Stress at load W_1, $-\frac{a_1r_1}{Z}$ Stress at support R, $\frac{m}{Z}$ Stress at load W_2, $-\frac{a_2r_2}{Z}$ The greatest of these is the maximum stress.

Deflection of Beam Uniformly Loaded for Part of Its Length. — In the following formulas, all lengths are in inches and all weights in pounds. W = total load; L = total length between supports; E = modulus of elasticity; I = moments of inertia of beam section; a = fraction of length of beam at each end, that is not loaded; f = deflection.



$$f = \frac{WL^3}{EI\,384\,(1-2a)}(5 - 24a^2 + 16a^4)$$

The expression for maximum bending moment is: $M_{max.} = \frac{1}{8}WL(1+2a)$. These formulas apply to simple beams resting on supports at the ends.

Beams of Uniform Strength Throughout Their Length. — In nearly all cases, the bending moment in a beam is not uniform throughout its length, but varies. Therefore, a beam of uniform cross-section which is made strong enough at its most strained section, will have an excess of material at every other section. Sometimes it may be desirable to have the cross-section uniform, while in other cases the metal can be more advantageously distributed if the beam is so designed that its cross-section varies from point to point, so that it is at every point just great enough to take care of the bending stresses at that point. A table is given showing beams

Stresses and Deflections in Beams

Deflections	
General Formula for Deflections at any Point	Deflections at Critical Points
Between point A and load, $y = \frac{Wx^2}{96\,EI}(9\,l - 11\,x)$ Between point B and load, $y = \frac{Wv}{96\,EI}(3\,l^2 - 5\,v^2)$	Maximum deflection is at $v = 0.4472\,l$, and is $\frac{Wl^3}{107.33\,EI}$ Deflection at load, $\frac{7}{768}\frac{Wl^3}{EI}$
Between R_1 and W_1, $y = \frac{w}{6\,EI}\left\{(l_1 - w)(l_1 + w)\,r_1 - \frac{W_1b_1^3}{l_1}\right\}$ Between R and W_1, $y = \frac{u}{6\,EIl_1}[W_1a_1b_1(l_1 + a_1) - W_1a_1u^2 - m(2\,l_1 - u)(l_1 - u)]$ Between R and W_2, $y = \frac{x}{6\,EIl_2}[W_2a_2b_2(l_2 + a_2) - W_2a_2x^2 - m(2\,l_2 - x)(l_2 - x)]$ Between R_2 and W_2, $y = \frac{v}{6\,EI}\left\{(l_2 - v)(l_2 + v)\,r_2 - \frac{W_2b_2^3}{l_2}\right\}$	Deflection at load W_1, $\frac{a_1b_1}{6\,EIl_1}[2\,a_1b_1W_1 - m(l_1 + a_1)]$ Deflection at load W_2, $\frac{a_2b_2}{6\,EIl_2}[2\,a_2b_2W_2 - m(l_2 + a_2)]$ This case is so complicated that convenient general expressions for the maximum deflections cannot be obtained.

in which the load is applied in different ways and which are supported by different methods, and the shape of the beam required for uniform strength is indicated. It should be noted that the shape given is the theoretical shape required to resist bending only. It is apparent that sufficient cross-section of beam must also be added either at the points of support (in the case of beams supported at both ends), or at the point of application of the load (in the case of beams loaded at one end), to take care of the vertical shear.

It should be noted that the theoretical shapes of the beams given in the tables on the two following pages are based on the stated assumptions of uniformity of width or depth of cross-section, and unless these are observed in the design, the theoretical outlines do not apply without modifications. For example, in a cantilever with the load at one end, the outline is a parabola only when the width of the beam is uniform. It is not correct to use a strictly parabolic shape when the thickness is not uniform, as, for instance, when the beam is made of an I- or T-section. In such cases, some modification may be necessary; but it is evident that whatever the shape adopted, the correct depth of the section can be obtained by an investigation of the bending moment and the shearing load at a number of points, and then a line can be drawn through the points thus ascertained, which will provide for a beam of practically uniform strength whether the cross-section be of uniform width or not.

Beams of Uniform Strength Throughout Their Length

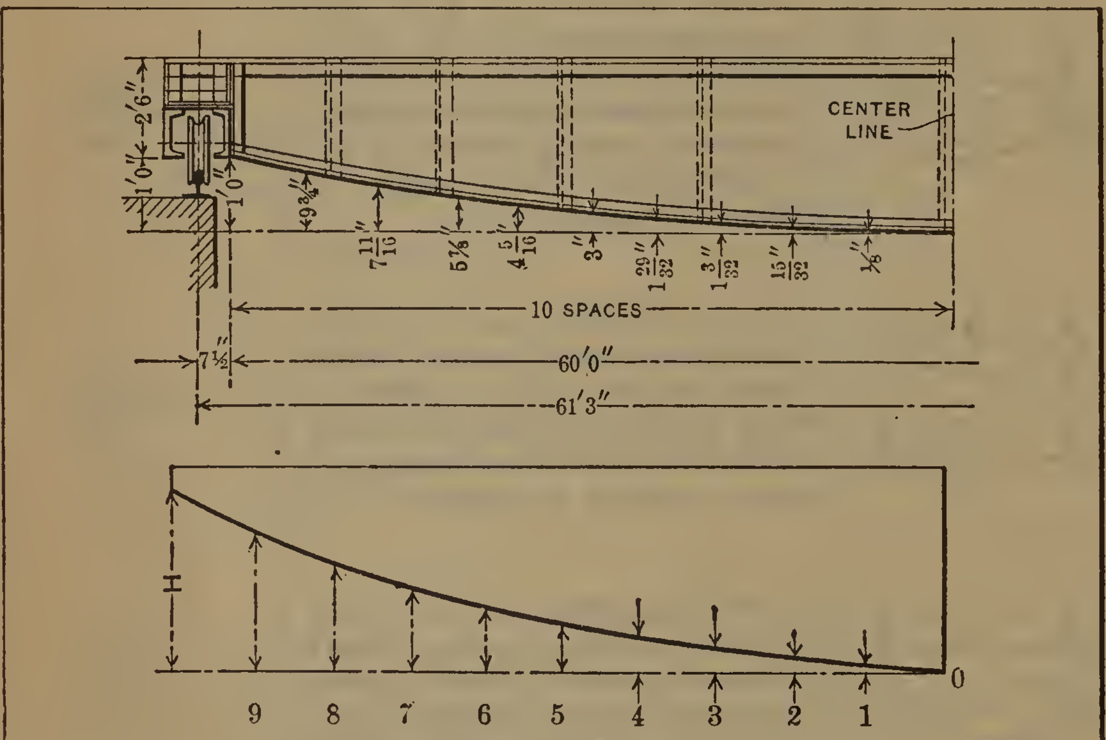
(All loads in pounds, all dimensions in inches.)

Type of Beam	Description	P = Carrying Capacity S = Safe Stress per Square Inch
	Load at one end. Width of beam uniform. Depth of beam decreasing towards loaded end. Outline of beam-shape, parabola with vertex at loaded end.	$P = \frac{Sbh^2}{6l}$
	Load at one end. Width of beam uniform. Depth of beam decreasing towards loaded end. Outline of beam, one-half of a parabola with vertex at loaded end. Beam may be reversed so that upper edge is parabolic.	$P = \frac{Sbh^2}{6l}$
	Load at one end. Depth of beam uniform. Width of beam decreasing towards loaded end. Outline of beam triangular, with apex at loaded end.	$P = \frac{Sbh^2}{6l}$
	Beam of *approximately* uniform strength. Load at one end. Width of beam uniform. Depth of beam decreasing towards loaded end, but not tapering to a sharp point.	$P = \frac{Sbh^2}{6l}$
	Uniformly distributed load. Width of beam uniform. Depth of beam decreasing towards outer end. Outline of beam, right-angled triangle.	$P = \frac{Sbh^2}{3l}$
	Uniformly distributed load. Depth of beam uniform. Width of beam gradually decreasing towards outer end. Outline of beam is formed by two parabolas which tangent each other at their vertices at the outer end of the beam.	$P = \frac{Sbh^2}{3l}$

Beams of Uniform Strength Throughout Their Length

Type of Beam	Description	P = Carrying Capacity S = Safe Stress per Square Inch
	Beam supported at both ends. Load concentrated at any point. Depth of beam uniform. Width of beam maximum at point of loading. Outline of beam, two triangles with apexes at points of support.	$P = \frac{Sbh^2l}{6\,ac}$
	Beam supported at both ends. Load concentrated at any point. Width of beam uniform. Depth of beam maximum at point of loading. Outline of beam is formed by two parabolas with their vertexes at points of support.	$P = \frac{Sbh^2l}{6\,ac}$
	Beam supported at both ends. Load concentrated in the middle. Depth of beam uniform. Width of beam maximum at point of loading. Outline of beam, two triangles with apexes at points of support.	$P = \frac{2\,Sbh^2}{3\,l}$
	Beam supported at both ends. Load concentrated at center. Width of beam uniform. Depth of beam maximum at point of loading. Outline of beam, two parabolas with vertices at points of support.	$P = \frac{2\,Sbh^2}{3\,l}$
	Beam supported at both ends. Load uniformly distributed. Depth of beam uniform. Width of beam maximum at center. Outline of beam, two parabolas with vertexes at middle of beam.	$P = \frac{4\,Sbh^2}{3\,l}$
	Beam supported at both ends. Load uniformly distributed. Width of beam uniform. Depth of beam maximum at center. Outline of beam one-half of an ellipse.	$P = \frac{4\,Sbh^2}{3\,l}$

Crane Girders with Curved Lower Chords. — An example of a design which makes use of the principles of beams of uniform strength is found in the ordinary fish-belly type of crane girder. When laying out crane girders, the accompanying tables will be found convenient. The engraving will explain the use of the tables. A crane girder having a span of 61 feet 3 inches has been assumed as an example. The curved part has a span of 60 feet; one-half of this distance, or 30 feet, is divided for the convenience of the templet makers into ten spaces of 3 feet each. The end ordinate, assumed here to be 1 foot, will be found at the extreme left of the tables under the heading H. The lengths of the remaining nine ordinates follow in order. For short spans, say about 30 feet, it is most convenient to divide the base of the curve into five spaces, as it is the usual practice to give ordinates about every 3 feet. In this case, we would use only every other ordinate in the tables, or, beginning with the left-hand column, the ordinates would be as found in the columns headed H, 8, 6, 4 and 2.



The tables are calculated from the formula:

$$X = H \times (M^2 \div N^2)$$

in which H = end ordinate; X = required ordinate; N = number of equal spaces into which the base line is divided; M = number of spaces from 0 to the required ordinate. When $N = 10$, as in the case for which the tables are calculated, $N^2 = 100$, and

$$X = H \times 0.01\, M^2.$$

Hence, ordinate No. 8 equals $H \times 0.01 \times 64 = 0.64\, H$. Ordinate No. 4 equals $H \times 0.01 \times 16 = 0.16\, H$.

Opinions vary considerably as to the allowable working stress in crane girders. Many cranes have girders which are designed for a stress of only 8000 pounds per square inch, while in others the stress will be over 14,000 pounds. However, a general factor of safety of 5 is the most usual and desirable in crane work, and if that factor of safety is adopted, the working stress should be anywhere from 11,000 to 12,000 pounds per square inch.

* The strength of large timbers depends chiefly upon the density or weight per cubic foot of the dry wood and upon the character, size, number and location of defects. "Dense" Douglas fir of the "No. 1 structural grade" shows on one end an average of at least six annual rings per inch and at least one-third "summer wood," measured over 3 inches on a line extending from the pith to the corner farthest from the pith when the least dimension of the timber is 5 inches or more. The point where the 3-inch line begins is found by the formula $A = \frac{1}{2} D - 2$, where A = distance in inches from pith to beginning of 3-inch line and D = minimum dimension of timber in inches. The "No. 2 structural grade" for Douglas fir includes timbers not passing the No. 1 grade, because (1) there is less density than required or (2) greater defects than are permitted.

† The term "southern yellow pine" includes the species known heretofore as long-leaf pine, short-leaf pine, loblolly pine, Cuban pine and pond pine. "Dense" southern yellow pine shows on either end an average of at least six annual rings per inch and at least one-third summer wood, or else the greater number of rings shows at least one-third summer wood all as measured over the third, fourth, and fifth inches of a radial line extending from the pith. Wide-ringed material, excluded by this rule, is acceptable, provided the amount of summer wood measured as previously specified is at least one-half. "Sound" southern yellow pine includes pieces without any ring or summer wood requirement.

Relation of Depth to Span of a Girder. — When in the design of a girder or cantilever, the specifications do not prescribe a particular depth of girder, the accompanying table of relation between depth and span will be found useful. The table is directly applicable when the girder is symmetrical in section about its neutral axis, and for a modulus of elasticity of 29,000,000, which is very general for structural shapes. The deflections used for calculating the table are those in most general use, being 1 inch per 100 feet span, or $\frac{L}{1200}$, and 2 inches per 100 feet span, or

Relation Between Depth of Girder and Length of Span

(L=length of span in inches)

Conditions	Safe Stress, Pounds per Square Inch	Depth, Inches
Beam supported at ends; load concentrated at middle; deflection, $L \div 1200$ or 1 inch per 100 feet.	10,000	$L \div 14.5$
	12,500	$L \div 11.6$
	16,000	$L \div 9.05$
	20,000	$L \div 7.25$
Beam supported at ends; load concentrated at middle; deflection, $L \div 600$ or 2 inches per 100 feet.	10,000	$L \div 29.0$
	12,500	$L \div 23.2$
	16,000	$L \div 18.1$
	20,000	$L \div 14.5$
Beam supported at ends; load uniformly distributed; deflection, $L \div 1200$ or 1 inch per 100 feet.	10,000	$L \div 11.6$
	12,500	$L \div 9.3$
	16,000	$L \div 7.25$
	20,000	$L \div 5.8$
Beam supported at ends; load uniformly distributed; deflection, $L \div 600$ or 2 inches per 100 feet.	10,000	$L \div 23.2$
	12,500	$L \div 18.6$
	16,000	$L \div 14.5$
	20,000	$L \div 11.6$
Cantilever; load concentrated at end; deflection, $L \div 1200$ or 1 inch per 100 feet.	10,000	$L \div 3.625$
	12,500	$L \div 2.9$
	16,000	$L \div 2.27$
	20,000	$L \div 1.81$
Cantilever; load concentrated at end; deflection, $L \div 600$ or 2 inches per 100 feet.	10,000	$L \div 7.25$
	12,500	$L \div 5.8$
	16,000	$L \div 4.54$
	20,000	$L \div 3.62$
Cantilever; load uniformly distributed; deflection, $L \div 1200$ or 1 inch per 100 feet.	10,000	$L \div 4.83$
	12,500	$L \div 3.87$
	16,000	$L \div 3.03$
	20,000	$L \div 2.42$
Cantilever; load uniformly distributed; deflection, $L \div 600$ or 2 inches per 100 feet.	10,000	$L \div 9.66$
	12,500	$L \div 7.74$
	16,000	$L \div 6.06$
	20,000	$L \div 4.84$

$\frac{L}{600}$, L being in inches. The lower limit is used where stiffness is necessary, and the higher limit where stiffness is not of primary importance.

If the modulus of elasticity is other than that used in these calculations, the divisor of the expression in the last column of the table will be directly proportional to the value of the modulus. For each condition of loading, the divisor is inversely proportional to the assumed safe stresses.

Having arrived at the required depth for a given deflection, it is an easy matter to find a suitable section for the given stress; but in all cases where exact work is required, the actual deflection and stress should be obtained after the design has been completed.

Strength of Channels. — Experiments on standard channels carried out by Bach (published in 1909) show that the regular bending formula for beams freely supported at their ends and loaded in the center gives too high a value for the strength of structural channels. The experiments show that the amount by which the value obtained from the formula is greater than that obtained by experiments, is, for channels 4¾ inches high, 7 per cent; for channels 8¾ inches high, 18 per cent; and for channels 11¾ inches high, 26 per cent. These values are those found when the load is assumed to be applied in the center line of the web of the channel as shown in Fig. 1. If the load is placed along the line of the vertical neutral axis of the channel as shown in Fig. 2, the permissible load according to the beam formula is 10, 25.5 and 34 per cent greater than that shown by the experiments. These experiments, therefore, indicate that when the usual formulas are employed in calculations, for channels or other structural shapes, a liberal factor of safety should be allowed in order to compensate for the difference of the results given by the formula and those of actual experiments. It should be noted that the formula for bending is fully correct whenever the section of the member is such that the load is fully distributed over the whole sectional area, as in a rectangular section, Fig. 3; but in the case of channels as well as many other structural shapes, the load is not, as a rule, properly distributed over the whole section, but stresses certain portions of the section in a higher degree than others.

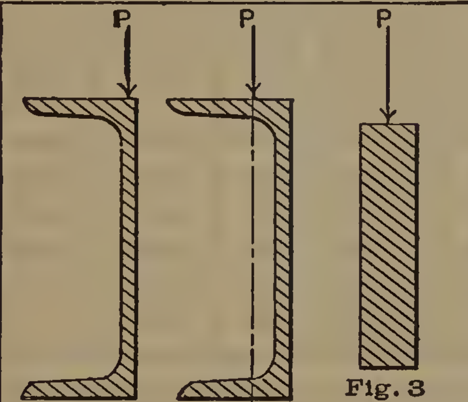

Fig. 1 Fig. 2 Fig. 3

Strength of Columns or Struts. — When a body that has considerable length in proportion to its width, breadth, or diameter is subjected to compression stresses, the ordinary formula for compression is not applicable, because bending stresses are set up on account of the length of the column or strut. The accompanying table gives formulas for calculating the ultimate load in pounds per square inch for columns. These formulas are based on the Rankine formula which is the one generally used by engineers in the design of columns unless the latter are unusually slender. When the length of a compressive member exceeds 8 or 10 times its smallest lateral dimension it is ordinarily known as a column, strut or post. Columns may, for the purpose of analysis, be divided into *short columns* and *long columns*. Short columns fail when the combined bending and compressive stresses reach the yield point of the material, but with long columns, failure occurs by buckling, before the load reaches the elastic limit. The *slenderness ratio* of a column is found by dividing the length by the least radius of gyration (l/r), the length of the column being in inches since the radius of gyration is commonly given in inches. The Rankine formula is generally applied for slenderness ratios between

20 and 100 and sometimes for ratios up to 120. In general, when the value of l/r exceeds 100, columns begin to fail by buckling, although the ratio varies according to the material and the support at the ends, as explained in the following: For ratios of l/r from 20 to about 100, there is little difference in the ultimate loads, especially for columns having fixed, flat, and hinged ends; and the same formulas may be applied when the ratios do not exceed the values given.

Euler's Formulas for Slender Columns. — Euler's formulas (see accompanying table) are commonly applied instead of Rankine's when the slenderness ratio of a column exceeds certain values which depend not only upon the material but upon whether the ends are flat, hinged, rounded, or fixed. According to one series of experiments, Euler's formulas should be used when the values of l/r exceed the following ratios for columns of different materials: Structural steel with flat ends, 195; with hinged ends, 155; round ends, 120. Cast iron with flat ends, 120; hinged ends, 100; round ends, 75. Oak with flat ends, 130. The difference in loading capacities for different values of l/r is shown by the accompanying table, "Ultimate Loads on Columns for Different Ratios of Slenderness." This table represents tests made at the Pencoyd Iron Works on wrought-iron columns.

Ultimate Loads on Columns for Different Ratios of Slenderness

Ratio l/r	Fixed Ends	Flat Ends	Hinged Ends	Round Ends	Ratio l/r	Fixed Ends	Flat Ends	Hinged Ends	Round Ends
20	46,000	46,000	46,000	44,000	260	11,000	9800	6500	3800
60	36,000	36,000	36,000	30,500	300	9,000	7200	5000	2800
100	30,000	29,800	28,000	20,000	340	7,000	5100	4000	2100
140	25,500	23,500	21,000	12,800	380	5,800	3500	3000	1700
180	20,000	16,800	12,800	7,500	420	4,800	2500	2300	1300
220	15,000	12,700	8,800	5,000	440	4,300	2200	2100	....

Eccentrically Loaded Columns. — In the application of the column formulas previously referred to, it is assumed that the action of the load coincides with the axis of the column. If the load is offset relative to the column axis, the column is said to be eccentrically loaded, and its strength is then calculated by using a modification of the Rankine formula, the quantity cz/r^2 being added to the denominator, as shown in the table on the next page. This modified formula is applicable to columns having a slenderness ratio varying from 20 or 30 to about 100.

Pipe Columns. — The allowable compressive stress for steel pipe columns may be determined from the formula:

$$S = 15{,}200 - 58\,L \div R$$

in which S = allowable compressive stress in pounds per square inch; L = length of column in inches; R = radius of gyration in inches. This formula is applicable to steel pipe columns with flat ends. No columns should be used having an unsupported length greater than 120 times its radius of gyration. The formula is based upon the requirements of the New York Building Code.

A similar formula, based upon the Chicago Building Ordinances, is:

$$S = 16{,}000 - 70\,L \div R$$

in which the letters denote the same quantities as in the previous formula.

Flat Stayed Surfaces. — In many cases, large flat areas are held against pressure by stays distributed at regular intervals over the surface. In boiler work, these stays are usually screwed into the plate and the projecting end riveted over to insure

Rankine's and Euler's Formulas for Columns

p = ultimate load in lbs. per square inch; P = total ultimate load in lbs.
S = ultimate compressive strength of material in pounds per square inch;
l = length of column or strut in inches;
r = least radius of gyration in inches; $r^2 = \frac{\text{moment of inertia}}{\text{area of section}}$;
I = least moment of inertia;
E = modulus of elasticity of material;
c = distance in inches from neutral axis of cross-section to side under compression;
z = distance in inches from axis of load to axis coinciding with center of gravity of cross-section.

Rankine's Formulas

Formulas Modified for Eccentrically Loaded Columns

Material *	Both Ends of Column Fixed	One End Fixed and One End Rounded	Both Ends Rounded
Steel..........	$p = \dfrac{S}{1 + \dfrac{l^2}{25{,}000\ r^2} + \dfrac{cz}{r^2}}$	$p = \dfrac{S}{1 + \dfrac{l^2}{12{,}500\ r^2} + \dfrac{cz}{r^2}}$	$p = \dfrac{S}{1 + \dfrac{l^2}{6250\ r^2} + \dfrac{cz}{r^2}}$

* For other materials such as cast iron, etc., use the Rankine formulas given in the upper table and add to the denominator the quantity $\frac{cz}{r^2}$.

Euler's Formulas for Slender Columns

Both Ends of Column Fixed	One End Fixed and One End Rounded	Both Ends Rounded	One End Fixed and One End Free
$P = \dfrac{4\pi^2 IE}{l^2}$	$P = \dfrac{2\pi^2 IE}{l^2}$	$P = \dfrac{\pi^2 IE}{l^2}$	$P = \dfrac{\pi^2 IE}{4 l^2}$

To find the total safe load for a given section, multiply the value of p (as found by any of the above formulas), by the area of the section and divide by a suitable factor of safety. (See table "General Factors of Safety.")

steam tightness. The U. S. Board of Supervising Inspectors and the American Boiler Makers Association rules give the following formula for flat stayed surfaces:

$$P = \frac{C \times t^2}{S^2}$$

in which P = pressure in pounds per square inch;

C = a constant which equals 112, for plates 7/16 inch and under; 120, for plates over 7/16 inch thick; 140, for plates with stays having a nut and bolt on the inside and outside; and 160, for plates with stays having washers of at least one-half the thickness of the plate, and with a diameter at least one-half of the greatest pitch.

t = thickness of plate in 16ths of an inch (thickness = 7/16, $t = 7$);

S = greatest pitch of stays in inches.

Strength of Flat Plates. — Exact formulas for finding the bending moments of flat plates supported along their edges and subjected to stresses created by pressures normal to their surfaces have not been determined. The formulas given by

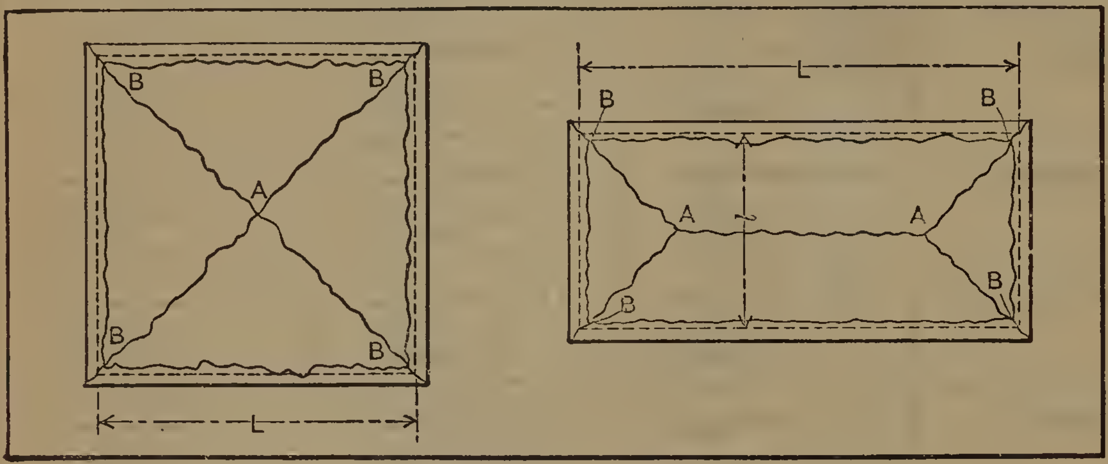

Fig. 1 Fig. 2

different authorities are founded on assumptions and should be considered as approximations only; they should be used with caution, as the results obtained are not likely to be very accurate.

A square cast-iron plate fixed or rigidly held at the edges and loaded with a uniformly distributed load, or a load concentrated at the center, would be likely to fail as shown in Fig. 1. It would first fracture along the diagonal lines from A to B and then fail at or near the fixed edges along lines BB. The plate might also shear off along the edges BB, depending upon the method of loading and the thickness of the plate. If the plate were merely supported along all the four edges, but not rigidly held, it would be likely to fail by breaking along the diagonal lines AB only.

In Fig. 2 is illustrated the probable manner of failure of a flat rectangular plate of cast iron, loaded with a uniformly distributed load. The plate, if secured along all the four edges, would probably fail by fracturing along the center line AA of the long axis of the plate and along the diagonal lines AB, and then fail at or near the edges of the support along the lines BB. If the plate were merely supported along all four edges, it would fail simply by fracturing along the center line AA and the diagonal lines AB. A plate firmly secured at the edges offers greater resistance to the stress created by the load than does a plate merely supported at the edges. While the formulas given in the following are approximate only, it is important that formulas be deduced and used for designs of this character, because they indicate, in a general way, the dimensions required, and the factor of safety assumed will always be taken large enough so that, practically, the approximate nature of the formulas does not detract from their value.

Square and Rectangular Flat Plates. — As the formulas of different authorities vary, formulas giving the higher or safer values have, as a rule, been selected. All of the flat-plate formulas given apply to cast iron, since they are usually required for this material by designers. In the following formulas: W = total load in pounds; P = load per square inch of surface, in pounds; L = span, or distance between supports, in inches; S = fiber stress in pounds per square inch; t = thickness of plate in inches. For rectangular plates, L and l are the long and short spans, or distances between the supported edges, respectively.

1. Square flat plate, supported at all four edges, with a load uniformly distributed over the unsupported surface of the plate. (Based on Grashof's formulas.)

$$W = 3.56\, St^2 \qquad S = 0.28\frac{W}{t^2} = 0.28\frac{PL^2}{t^2}$$

$$L = 1.89\, t\sqrt{\frac{S}{P}} \qquad t = 0.53\sqrt{\frac{W}{S}} = 0.53\, L\sqrt{\frac{P}{S}}$$

2. Square flat plate, firmly secured along all four edges, with a load uniformly distributed over the unsupported surface of the plate. (Based on Unwin's formulas.)

$$W = 4\, St^2 \qquad S = 0.25\frac{W}{t^2} = 0.25\frac{PL^2}{t^2}$$

$$L = 2\, t\sqrt{\frac{S}{P}} \qquad t = 0.5\sqrt{\frac{W}{S}} = 0.5\, L\sqrt{\frac{P}{S}}$$

3. Square flat plate, supported at all four edges, with a load W concentrated at the center. (Based on Grashof's formulas.)

$$W = 0.67\, St^2 \qquad S = 1.5\frac{W}{t^2} \qquad t = 1.23\sqrt{\frac{W}{S}}$$

4. Square flat plate, firmly secured along all four edges, with a load W concentrated at the center. (Based on Grashof's formulas.)

$$W = 0.76\, St^2 \qquad S = 1.31\frac{W}{t^2} \qquad t = 1.14\sqrt{\frac{W}{S}}$$

5. Flat rectangular plate, supported at all four edges, with a load uniformly distributed over the unsupported surface of the plate. (Based on Grashof's formulas.)

$$W = 1.77\frac{St^2(L^2+l^2)}{Ll} \qquad P = 1.77\frac{St^2(L^2+l^2)}{L^2l^2}$$

$$S = 0.56\frac{WLl}{t^2(L^2+l^2)} \qquad t = 0.75\sqrt{\frac{WLl}{S(L^2+l^2)}}$$

6. Flat rectangular plate, firmly secured at all four edges, with a load uniformly distributed over the unsupported area of the plate. (Based on Grashof's formulas.)

$$W = 2.67\frac{St^2(L^2+l^2)}{Ll} \qquad P = 2.67\frac{St^2(L^2+l^2)}{L^2l^2}$$

$$S = 0.375\frac{WLl}{t^2(L^2+l^2)} \qquad t = 0.62\sqrt{\frac{WLl}{S(L^2+l^2)}}$$

7. Flat rectangular plate, supported at all four edges, with a load W concentrated at the center. (Based on Grashof's formulas.)

$$W = 0.33\,\frac{St^2(L^2+l^2)}{Ll} \qquad S = \frac{3\,WLl}{t^2(L^2+l^2)} \qquad t = 1.73\sqrt{\frac{WLl}{S(L^2+l^2)}}$$

8. Flat rectangular plate, firmly secured at all four edges, with a load W concentrated at the center. (Based on Grashof's formulas.)

$$W = 0.38\,\frac{St^2(L^2+l^2)}{Ll} \qquad S = 2.62\,\frac{WLl}{t^2(L^2+l^2)} \qquad t = 1.6\sqrt{\frac{WLl}{S(L^2+l^2)}}$$

Formulas for Circular Flat Plates. — In the following formulas:

W = total load in pounds;
P = load in pounds per square inch;
R = radius of plate, to the supporting edge, in inches;
S = fiber stress in pounds per square inch;
t = thickness of plate in inches;
d = deflection at center of plate in inches;
E = modulus of elasticity.

1. Circular flat plate, supported all around the edge, with a load uniformly distributed over the unsupported area of the plate. (Based on Reuleaux's formulas.)

$$W = 3.14\,St^2 \qquad S = \frac{PR^2}{t^2} = 0.318\,\frac{W}{t^2}$$

$$R = t\sqrt{\frac{S}{P}} \qquad t = R\sqrt{\frac{P}{S}} = 0.56\sqrt{\frac{W}{S}}$$

$$P = \frac{St^2}{R^2} \qquad d = \frac{5\,PR^4}{6\,Et^3} = 0.265\,\frac{WR^2}{Et^3}$$

2. Circular flat plate, firmly secured all around the edge, with a load uniformly distributed over the unsupported area of the plate. (Based on Reuleaux's formulas.)

$$W = 4.7\,St^2 \qquad S = 0.67\,\frac{PR^2}{t^2} = 0.21\,\frac{W}{t^2}$$

$$R = 1.22\,t\sqrt{\frac{S}{P}} \qquad t = 0.81\,R\sqrt{\frac{P}{S}} = 0.46\sqrt{\frac{W}{S}}$$

$$P = 1.5\,\frac{St^2}{R^2} \qquad d = \frac{PR^4}{6\,Et^3} = 0.053\,\frac{WR^2}{Et^3}$$

3. Circular flat plate, supported all around the edge, with a load concentrated at the center of the plate upon a circular area with radius r. (Based on Bach's formulas.)

$$W = 0.7\,\frac{St^2}{1-\dfrac{2\,r}{3\,R}} \qquad S = 1.43\,\frac{W\left(1-\dfrac{2\,r}{3\,R}\right)}{t^2}$$

$$t = 1.2\sqrt{\frac{W\left(1-\dfrac{2\,r}{3\,R}\right)}{S}} \qquad d = 0.5\,\frac{WR^2}{Et^3}$$

4. Circular flat plate, firmly secured all around the edge, with a load concentrated at the center of the plate upon a circular area with radius r. (Based on Grashof's formulas.)

$$W = 2.36 \frac{St^2}{\text{hyp. log} \dfrac{R}{r}} \qquad S = 0.424 \frac{W}{t^2} \text{hyp. log} \frac{R}{r}$$

$$t = 0.65 \sqrt{\frac{W \text{ hyp. log} \dfrac{R}{r}}{S}} \qquad d = 0.48 \frac{WR^2}{Et^3}$$

Strength of Cylinders Subjected to Internal Pressure. — In low-pressure work, the general practice is to make the thickness of the metal equal to the internal diameter in inches times the pressure in pounds per square inch, and this product divided by twice the allowable working stress of the material. To this is added a variable quantity to allow for unsound castings and possible unknown stresses. Hence, if t = thickness in inches; d = inside diameter in inches; P = pressure in pounds per square inch; S = allowable tensile stress in pounds per square inch, then:

$$t = \frac{dP}{2S}$$

To the value of t thus obtained must then be added an amount to allow for variations in the material and possible excessive stresses when the cylinder is in operation.

Find the thickness required for a cast-iron cylinder, 15 inches in diameter (inside), to withstand an internal pressure of 200 pounds per square inch. Assume the allowable working stress for cast iron to be 4000 pounds per square inch. Then:

$$t = \frac{15 \times 200}{2 \times 4000} = \frac{3}{8} \text{ inch.}$$

The material being cast iron, a liberal allowance must be added to this thickness to take care of possible defects in the casting.

The formula given should be used only for low pressures. When the pressures rise, the Barlow formula is preferable. This formula is similar in form to the one already given, but it gives results quite different when applied to tubes and pipes having walls of considerable thickness in proportion to the diameter, because the Barlow formula is expressed in terms of the outside diameter, whereas the formula given above is expressed in terms of the inside diameter. The Barlow formula is:

$$t = \frac{DP}{2S}$$

in which t = thickness in inches; D = outside diameter in inches; P = pressure in pounds per square inch; S = allowable tensile stress in pounds per square inch.

This formula is based on assumptions which cannot be considered as theoretically correct, but the error is on the side of safety, and experiments have proved that of the various formulas proposed for the strength of tubes and pipes subjected to moderate pressures, the Barlow formula gives the most reliable results.

The average ultimate tensile strength of seamless steel tubes may be assumed at 55,000 pounds per square inch; that for butt-welded steel pipe at 40,000; that for lap-welded steel pipe at 50,000; and that for wrought-iron pipe (butt-welded or lap-welded) at 28,000 pounds per square inch.

If seamless steel tubes are assumed to have a strength of 100 per cent, butt-welded steel pipe has a comparative strength of 73 per cent, and lap-welded steel pipe of 92 per cent. From this it will be seen that the strength of a butt-weld is only about 80 per cent of that of a lap-weld. The relative strengths of wrought-iron and steel pipe are as follows: Butt-welded wrought-iron pipe has 70 per cent of the strength of similar butt-welded steel pipe, and lap-welded wrought-iron pipe has 57 per cent of the strength of similar lap-welded steel pipe.

Cylinders Subjected to High Internal Pressure. — For high pressures, Lamé's formula is used. This formula is in its usual form,

$$t = r\left(\sqrt{\frac{S+P}{S-P}} - 1\right)$$

sometimes inconvenient to use. The following forms of the same formula obtained by substitution are often useful:

$$S = P\,\frac{R^2+r^2}{R^2-r^2} \qquad R = r\sqrt{\frac{S+P}{S-P}}$$

$$P = S\,\frac{R^2-r^2}{R^2+r^2} \qquad r = R\sqrt{\frac{S-P}{S+P}}$$

In these formulas:

S = maximum allowable fiber stress per square inch;
R = outer radius of cylinder in inches;
r = inner radius of cylinder in inches;
P = pressure within the cylinder in pounds per square inch;
$t = R - r$ = thickness of cylinder in inches.

A table of ratios of outside radius to inside radius of thick cylinders is given for convenience in calculating the dimensions of cylinders under high internal pressure without the use of the formulas. This table is based on the Lamé formula. As an example of the use of the table, assume that a cylinder of 10 inches inside diameter is to withstand a pressure of 2500 pounds per square inch; the material is cast iron, the allowable stress in this case being 6000 pounds per square inch. To solve the problem, locate the allowable stress per square inch in the left-hand column of the table and the working pressure at the top of the columns. Then find the ratio between the outside and inside radii in the body of the table. In this case, the ratio is 1.558, and hence the outside diameter of the cylinder should be 10×1.558, or about 15⅝ inches.

Unless very high-grade material is used and sound castings assured, cast iron should not be used for pressures exceeding 2000 pounds per square inch. When pressures exceed 2500 pounds per square inch, the packings are likely to leak and the valves and pipe fittings give trouble. It is, therefore, advisable to keep the pressure below this point, if possible. It is well to leave more metal in the bottom of a hydraulic cylinder than is indicated by the results of calculations, because a hole of some size must be cored in the bottom to permit the entrance of a boring bar when finishing the cylinder, and when this hole is subsequently tapped and plugged it often gives trouble if the precaution mentioned is not taken.

For steady or gradually applied stresses, the maximum allowable fiber stress S in the formulas above may be assumed from 3500 to 4000 pounds per square inch for cast iron; from 6000 to 7000 pounds per square inch for brass; and as 12,000 pounds per square inch for steel castings. For intermittent stresses, such as in cylinders for steam and hydraulic work, 3000 pounds per square inch for cast iron; 5000 pounds per square inch for brass; and 10,000 pounds per square inch for steel castings, is ordinarily used. These values give ample factors of safety.

Ratio of Outside Radius to Inside Radius, Thick Cylinders

Spherical Shells Subjected to Internal Pressure. — Let:

D = internal diameter of shell in inches;
P = internal pressure in pounds per square inch;
S = safe tensile stress per square inch;
t = the thickness of metal in the shell in inches. Then:

$$P\frac{\pi D^2}{4} = \pi DtS, \quad \text{and} \quad t = \frac{PD}{4S}$$

This formula also applies to hemi-spherical shells, such as the hemi-spherical head of a cylindrical container subjected to internal pressure, etc.

Example: — Find the thickness of metal required in the hemi-spherical end of a cylindrical vessel, 2 feet in diameter, subjected to an internal pressure of 500 pounds per square inch. The material is mild steel and a tensile stress of 10 000 pounds per square inch is allowable.

$$t = \frac{500 \times 2 \times 12}{4 \times 10{,}000} = 0.3 \text{ inch.}$$

If the radius of curvature of the dome head of a boiler or container subjected to internal pressure is made equal to the diameter of the boiler, the thickness of the cylindrical shell and of the spherical head should be made the same. For example, if a boiler is 3 feet in diameter, the radius of curvature of its head should be made 3 feet, if material of the same thickness is to be used and the stresses are to be equal in both the head and cylindrical portion.

Collapsing Pressures of Cylinders and Tubes Subjected to External Pressures. — The following formulas may be used for finding the collapsing pressures of modern lap-welded Bessemer steel tubes:

$$P = 86{,}670\frac{t}{D} - 1386 \quad . \quad . \quad . \quad (1) \qquad\qquad P = 50{,}210{,}000\left(\frac{t}{D}\right)^3 \quad . \quad . \quad . \quad (2)$$

in which P = collapsing pressure in pounds per square inch; D = outside diameter of tube or cylinder in inches; t = thickness of wall in inches.

Formula (1) is for values of P greater than 580 pounds per square inch, and Formula (2) is for values of P less than 580 pounds per square inch. These formulas are substantially correct for all lengths of pipe greater than six diameters between transverse joints that tend to hold the pipe to a circular form. The pressure P found is the actual collapsing pressure, and a suitable factor of safety must be used. Ordinarily, a factor of safety of 5 is sufficient. In cases where there are repeated fluctuations of the pressure, vibration, shocks and other stresses, a factor of safety of from 6 to 12 should be used.

The table "Tubes Subjected to External Pressure" is based upon the requirements of the Steam Boat Inspection Service of the Department of Commerce and Labor and gives the permissible working pressures and corresponding minimum thickness of wall for long, plain, lap-welded and seamless steel flues subjected to external pressure only. The thicknesses in the table have been calculated from the formula:

$$T = \frac{[(F \times P) + 1386]\,D}{86{,}670}$$

in which D = outside diameter of flue or tube in inches; T = thickness of wall in inches; P = working pressure in pounds per square inch; F = factor of safety. The formula is applicable to working pressures greater than 100 pounds per square inch, to outside diameters from 7 to 18 inches, and to temperatures less than 650° F.

The Formulas (1) and (2) given on the preceding page were determined by Prof. R. T. Stewart, Dean of the Mechanical Engineering Department of the University of Pittsburg, in a series of experiments carried out at the plant of the National Tube Co., McKeesport, Pa. These tests occupied a period of four years. A full report of the details of these experiments will be found in a paper presented by Prof. Stewart before the American Society of Mechanical Engineers in May, 1906. The principal conclusions to be drawn from the results of this research may be briefly stated as follows:

The length of tube, between transverse joints tending to hold it to a circular form, has no practical influence upon the collapsing pressure of a commercial lap-welded steel tube, so long as this length is not less than about six times the diameter of the tube.

The apparent fiber stress under which the different tubes failed varied from about 7000 pounds per square inch for the relatively thinnest to 35,000 pounds per square inch for the relatively thickest walls. Since the average yield point of the material tested was 37,000 pounds and the tensile strength 58,000 pounds per square inch, it is evident that the strength of a tube subjected to external fluid collapsing pressure is not dependent alone upon the elastic limit or ultimate strength of the material from which it is made.

Tubes Subjected to External Pressure

RIVETING AND RIVETED JOINTS

Classes of Riveted Joints. — When the plates to be joined by riveting overlap each other and are held together by one or more rows of rivets, a *lap-joint* is formed. In a *butt-joint* the plates are in the same plane and are united by a cover plate or butt strap, which is riveted to each plate. A combination lap-joint consists of a cover plate inside or outside the lap, and three rows of rivets, the central row passing through the two plates and the cover, and having twice as many rivets as the other two rows. The term *single riveting* means one row of rivets in a lap-joint or one row on each side of a butt-joint; *double riveting* means two rows of rivets in a lap-joint or two rows on each side of the joint in butt riveting. Joints are also triple and quadruple riveted.

Pitch of Rivets. — The pitch is the distance from center to center of adjacent rivets. The pitch of rivets should be as large as possible without impairing the tightness of the joint when under pressure. For single-riveted lap-joints in the circular seams of boilers which have double-riveted longitudinal lap-joints:

$$\text{pitch} = d \times 2.25 = t \times 5, \text{ approximately,}$$

in which d = the actual diameter of rivet (in parallel hole); t = thickness of plate.

For double-riveted lap-joints:

$$\text{pitch} = 8\,t$$

The following formulas for determining the pitch are given by Unwin:

For single-riveted joints in single shear (mild steel):

$$\text{pitch} = 0.644\,\frac{d^2}{t} + d.$$

For single-riveted joints in double shear:

$$\text{pitch} = 1.13\,\frac{d^2}{t} + d.$$

For double-riveted joints in single shear (mild steel):

$$\text{pitch} = 1.288\,\frac{d^2}{t} + d.$$

For double-riveted joints in double shear:

$$\text{pitch} = 2.26\,\frac{d^2}{t} + d.$$

For triple-riveted joints with rivets in single shear (mild steel):

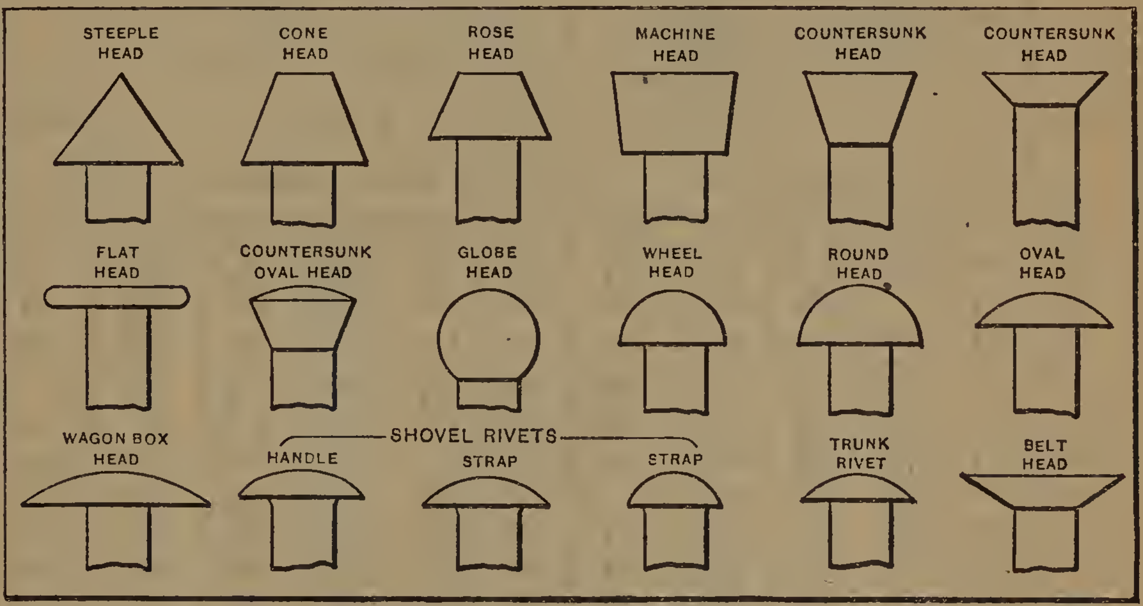
$$\text{pitch} = 1.93\,\frac{d^2}{t} + d.$$

For triple-riveted joints with rivets in double shear:

$$\text{pitch} = 3.30\,\frac{d^2}{t} + d.$$

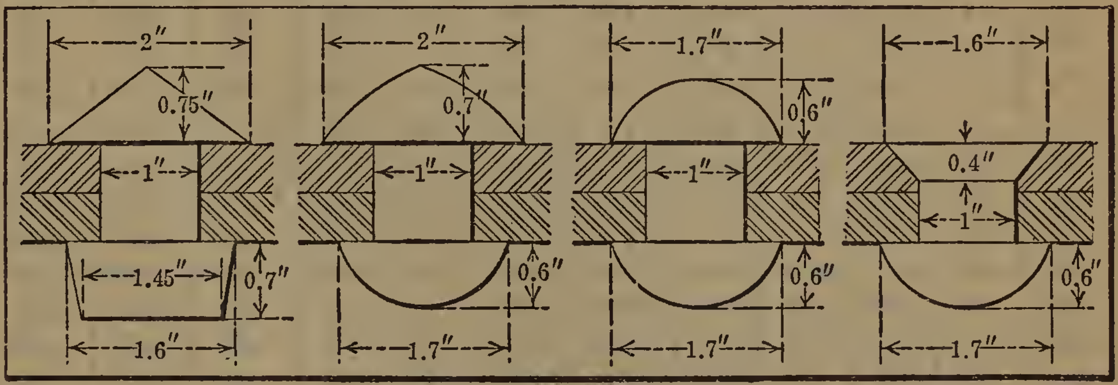
In the foregoing formulas, d = diameter of the driven rivet.

To secure a joint of maximum strength, the breadth of lap must be such as to prevent it from breaking zigzag. Tests have demonstrated that rupture is equally probable through a diagonal as through a transverse line, unless the net diagonal section exceeds the net section along the transverse line by 30 to 35 per cent. This corresponds to a diagonal pitch of $\frac{2}{3}P + \frac{d}{3}$, in which P is the straight pitch, and d, the diameter of the rivet hole. A general rule for the pitch between rows in staggered riveting is as follows: The pitch between rows should equal one-half the pitch of the rivets in a row, plus ¼ of the diameter of the rivet holes. The distance from the edge of the rivet hole to the edge of the plate should never be less than the rivet diameter.



Different Types of Rivet Heads

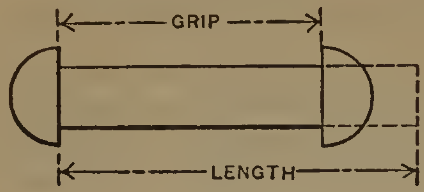
Rivet Diameter. — Rivet diameters for plates of given thickness range in practice from $d = 1.2\sqrt{t}$ to $d = 1.4\sqrt{t}$, in which d = diameter of the rivet and t = thickness of plate. The larger size is preferable for steel and single-riveted joints, and the smaller for iron and multiple-riveted joints.

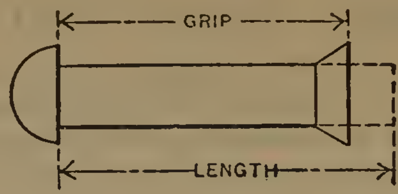


Proportions of Rivet Heads

Length and Proportions of Rivets. — In order to form the head and fill the clearance space in the rivet hole, the rivet should have a length in excess of the thickness of the plate equal to about three-fourths the diameter for countersunk head, and from 1.3 to 1.7 times the diameter for ordinary riveting. (See table, "Rivet Lengths for Forming Round and Countersunk Heads.") The proportions of rivet heads are given in the accompanying illustration (Unwin). The dimensions are given in terms of the diameter and represent the average conditions, the sizes varying more or less in different shops.

Rivet Lengths for Forming Round and Countersunk Heads





Grip in Inches	Round Head					Countersunk Head					Grip in Inches

General Rules for Rivet Spacing.—The following rules for rivet spacing (given by the Cambria Steel Co.) apply to bridge and structural work. The minimum center-to-center distance or pitch should not be less than three times the rivet diameter. In bridge work, the pitch should not exceed six inches, or sixteen times the thickness of the thinnest outside plate, except in special cases. The distance between the edge of any piece and the center of the rivet hole should not be less than 1 1/4 inch for 3/4- and 7/8-inch rivets, except in bars less than 2 1/2 inches wide; when practicable, this distance should be at least two rivet diameters for all sizes and should not exceed eight times the plate thickness. For flanges of girders and chords carrying floors, the pitch should not exceed four inches. For plates in compression, the pitch in the direction of the line of tress should not exceed sixteen times the thickness of the plate, and the pitch in a direction at right angles to the line of stress should not exceed thirty-two times the thickness, except for cover plates or top chords and end posts, in which the pitch should not exceed forty times the thickness. When rivets are adjacent to the corners of angles, etc., the space between the rivet center and the side of the adjacent leg of the angle, should not be less than one-half the diameter of the head plus 3/8 inch, for clearance. When there is a row of rivets in the adjacent side, the 3/8-inch clearance should be measured from the rivet heads.

Rivet Spacing for Angles

5/16	¼	5/8	8	12¼	1 1/16	2⅛	1⅞	2¾	5½	88
⅜	5/16	¾	9¼	14¼	1¼	2½	2⅛	3⅛	6¼	90
7/16	⅜	⅞	10½	16¼	1 7/16	2⅞	2⅜	3½	7	90
½	7/16	15/16	11	17	1½	3	2½	3¾	7½	88

Double- and Triple-riveted Butt-joints. — The types of joints most commonly used for the longitudinal seams in boiler work are the double-riveted and triple-riveted butt-joints, with double covering strips. Quadruple-riveted joints are also used to a considerable extent for high-pressure work, these joints having a somewhat higher efficiency than triple-riveted joints. Lap-joints are no longer used in the best class of work for longitudinal seams, as experience has shown that they become weakened by continued use and are liable to fracture. Single-riveted lap-joints are sufficiently strong for the girth seams, as the pressure exerted in this direction is only one-half of that carried by the longitudinal seams. (See table "Proportions of Double- and Triple-riveted Butt-joints.")

Rivet Steel. — Boiler rivet steel, according to the standard specifications of the American Society for Testing Materials, should be made by the open-hearth process and have the following physical properties: Tensile strength, from 45,000 to 55,000 pounds per square inch; minimum yield point, one-half the tensile strength; minimum percentage of rivet elongation for a length not less than four times the rivet diameter, 1,500,000 ÷ tensile strength, but not to exceed 30 per cent. The rivet shank should bend cold through 180 degrees or flat on itself without cracking on the outside of the bend. The rivet should withstand this same test after being heated to a light cherry red as seen in the dark (not less than 1200 degrees F.) and quenched in water the temperature of which is between 80 and 90 degrees F. The rivet head should flatten, while hot, to a diameter two and one-half times the diameter of the shank without cracking at the edges. The chemical composition of the rolled bar should be as follows: Manganese, 0.30 to 0.50 per cent; phosphorus, not over 0.04; and sulphur, not over 0.045 per cent. The analysis should be from a test ingot taken during the pouring of each melt.

Let p = pitch of rivets; d = diameter of driven rivets; η = efficiency or ratio of strength of joint to strength of solid plate; then: $\eta = \frac{p-d}{p}$.

Riveting Pressures. — The pressures required for hot riveting ordinarily range from 75,000 to 150,000 pounds per square inch of rivet area, depending upon the class of work and the relation between the rivet diameter and the total plate thickness. The data in the table "Pressures for Hot Riveting" is from R. D. Wood & Co. It is assumed that the rivet passes through only two thicknesses of plate having a maximum total thickness not much in excess of the rivet diameter. As the total plate thickness increases beyond the rivet diameter, the riveting pressure increases approximately in proportion to the square root of the thickness. Thus, if the total thickness of the plate is four times the rivet diameter, twice the riveting pressure given in the table would be required in order to fill the rivet hole thoroughly and do good work. Double the thickness of plate would increase the necessary power about 40 per cent. Approximately four or five times as much power is required to drive rivets cold as to drive them hot. Thus a machine which will drive ¾-inch hot rivets will usually drive ⅜-inch cold rivets.

Pressures for Hot Riveting

Rivet Diameter	Class of Work and Pressure in Tons			Rivet Diameter	Class of Work and Pressure in Tons		
	Boiler	Tank	Girder		Boiler	Tank	Girder
½	20	15	9	1⅛	75	60	38
⅝	25	18	12	1¼	100	70	45
¾	33	22	15	1½	125	85	60
⅞	45	30	22	1¾	150	100	75
1	60	45	30	....	......	......	......

Loss of Strength when Holes are not Reamed. — When holes are punched in heavy steel plates there is considerable loss of strength unless the holes are reamed after punching. Annealing after punching also restores the strength. The loss in strength due to punching varies from about 10 per cent to 30 per cent for plates varying from ¼ to ¾ inch thick. The loss in case of thin plates is very slight. When holes are punched, instead of being drilled, usually the diameter should be increased from 1/16 to ⅛ inch by reaming, in order to remove the inferior metal around the punched hole. According to Navy Department specifications all holes in boiler plates must be drilled with the plates in place.

Loads at which Slipping Occurs in Riveted Joints. — Owing to the contraction of rivets on cooling, the plates are drawn together tightly; spaces are also left between the rivets and the holes so that it is possible for the plates to slip before shearing the rivets. The load required to overcome the frictional resistance between the plates varies (according to Bach) from 14,000 to 30,000 pounds per square inch of rivet area at each pair of surfaces in contact. It is the practice in Europe to design boiler joints with reference to the resistance to slipping, as any appreciable movement of such joints will cause leakage.

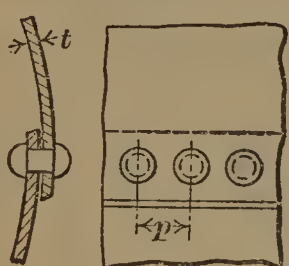
Elastic Limit of Riveted Boiler Joints. — Riveted boiler joints should cease to be steam-tight for some time before the internal pressure is equal to the elastic limit of the plate. If a boiler were stretched beyond the elastic limit of the material, the rivet holes would become stretched and the joints of the plates would be disturbed, resulting in large leakage from the rivet holes and seams. The elastic limit of riveted joints for the best quality of mild steel varies from 32,000 to 34,000 pounds per square inch and for an ordinary quality of mild steel, from 28,000 to 30,000 pounds per square inch. The elastic limit for the best quality of wrought iron varies from 24,000 to 26,000 pounds per square inch and for an ordinary quality, from 20,000 to 22,000 pounds per square inch.

Failure of Riveted Joints

A riveted joint may fail by shearing the rivets, tearing the plate between the rivets, crushing the rivets or plate, or by a combination of two or more of the foregoing causes. To determine the efficiency of a riveted joint, first calculate the breaking strength by the different ways in which it may fail. That method of failure giving the least result will show the actual strength of the joint. If this equals S_r and S equals the tensile strength of the solid plate, then the efficiency $= \frac{S_r}{S}$. In the following formulas, let,

d = diameter of rivets;
t = thickness of plate;
t_c = thickness of cover plates;
p = pitch of inner row of rivets;
P = pitch of outer row of rivets;
S = shearing strength of rivets;
T = tensile strength of plate;
C = crushing strength of rivets.

(All dimensions in inches; all stresses in pounds per square inch.)

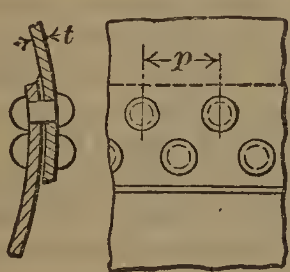


For Single-riveted Lap-joint

(1) Resistance to shearing one rivet $= \frac{\pi d^2}{4} S$

(2) Resistance to tearing plate between rivets $= (p - d)\,tT$

(3) Resistance to crushing rivet or plate $= dtC$

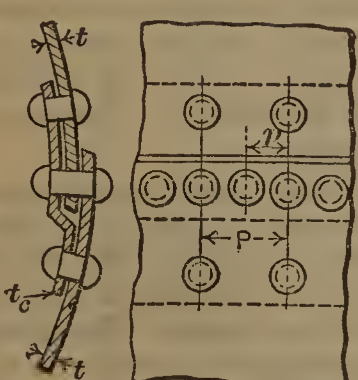


Double-riveted Lap-joint

(1) Resistance to shearing two rivets $= \frac{2\pi d^2}{4} S$

(2) Resistance to tearing between two rivets $= (p - d)\,tT$

(3) Resistance to crushing in front of two rivets $= 2\,dtC$



Single-riveted Lap-joint with Inside Cover Plate

(1) Resistance to tearing between outer row of rivets $= (P - d)\,tT$

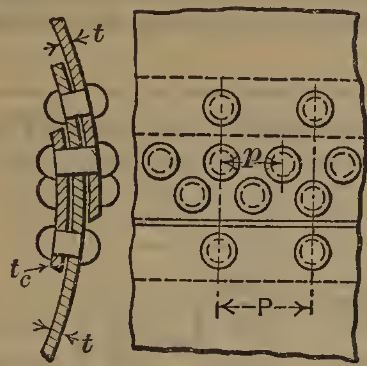
(2) Resistance to tearing between inner row of rivets, and shearing outer row of rivets $= (P - 2\,d)\,tT + \frac{\pi d^2}{4} S$

(3) Resistance to shearing three rivets $= \frac{3\,\pi d^2}{4} S$

(4) Resistance to crushing in front of three rivets $= 3\,t\,dC$

(5) Resistance to tearing at inner row of rivets, and crushing in front of one rivet in outer row $= (P - 2\,d)\,tT + t\,dC$

Failure of Riveted Joints



Double-riveted Lap-joint with Inside Cover Plate

(1) Resistance to tearing at outer row of rivets $= (P - d)\,tT$

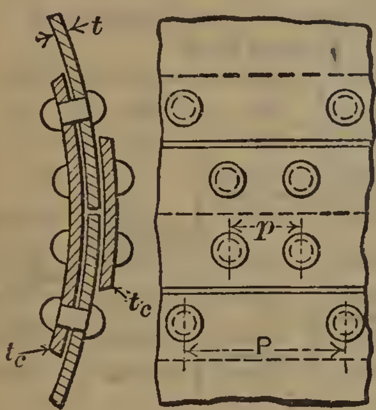
(2) Resistance to shearing four rivets $= \dfrac{4\,\pi d^2}{4} S$

(3) Resistance to tearing at inner row and shearing outer row of rivets

$$= (P - 1\tfrac{1}{2}\,d)\,tT + \frac{\pi d^2}{4} S$$

(4) Resistance to crushing in front of four rivets $= 4\,t\,dC$

(5) Resistance to tearing at inner row of rivets, and crushing in front of one rivet $= (P - 1\tfrac{1}{2}d)tT + t\,dC$



Double-riveted Butt-joint

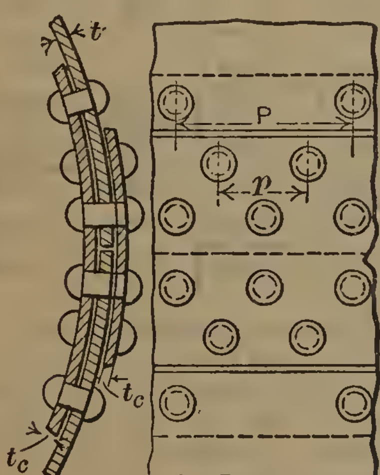
(1) Resistance to tearing at outer row of rivets $= (P - d)\,tT$

(2) Resistance to shearing two rivets in double shear and one in single shear $= \dfrac{5\,\pi d^2}{4} S$

(3) Resistance to tearing at inner row of rivets and shearing one rivet of the outer row $= (P - 2\,d)\,tT + \dfrac{\pi d^2}{4} S$

(4) Resistance to crushing in front of three rivets $= 3\,t\,dC$

(5) Resistance to tearing at inner row of rivets, and crushing in front of one rivet in outer row $= (P - 2\,d)\,tT + t\,dC$



Triple-riveted Butt-joint

(1) Resistance to tearing at outer row of rivets $= (P - d)\,tT$

(2) Resistance to shearing four rivets in double shear and one in single shear $= \dfrac{9\,\pi d^2}{4} S$

(3) Resistance to tearing at middle row of rivets and shearing one rivet

$$= (P - 2\,d)\,tT + \frac{\pi d^2}{4} S$$

(4) Resistance to crushing in front of four rivets and shearing one rivet $= 4\,dtC + \dfrac{\pi d^2}{4} S$

(5) Resistance to crushing in front of five rivets $= 4\,dtC + dt_cC$

Crushing Strength of Rivets. — The crushing strength of rivets and plates, in joints that fail by crushing, is found by experiment to be high and irregular. In some cases it has amounted to 150,000 pounds per square inch; in a few tests it has been less than 85,000 pounds per square inch. A value of 95,000 pounds may be used with safety for general calculations.

Shearing Value of Rivets — Bearing Value of Riveted Plates

All bearing values above or to the right of the upper zigzag lines are greater than double shear. Values between the upper and lower zigzag lines are less than double, and greater than single, shear. Values below and to the left of the lower zigzag lines are less than single shear.

Net Areas of Structural Angles. — When using the tables of net areas of structural angles, the length of the legs of the angles are added together and the sum of the lengths is first found in the left-hand column of the tables; then the thickness of the angle is found in the second column. The other columns then give the net areas after having deducted for one or two rivets of sizes as specified at the head of

Net Areas of Standard Angles

(The size of rivet holes is 1/8 inch larger than diameter of rivet)

the columns. The table entitled "Area Deducted for Various Sizes of Rivets and Thicknesses of Angles" is used for determining the net area of angles of dimensions not given in the previous table, or for rivet sizes not specified.

STRENGTH AND PROPERTIES OF STEEL WIRE

Wire Gages. — A great number of different wire gages known by numbers have been in use. In order to avoid confusion, it would be well if, in general, gage numbers could be avoided and the size of the wire required given in decimals of an inch. However, when this cannot be done, care should be taken to adhere to the gage numbers which have become practically standard for certain classes of wire. Upon the recommendation of the Bureau of Standards at Washington, a number of the principal wire manufacturers and consumers have agreed that it would be well to designate the American Steel & Wire Co.'s gage, which is the same as the Washburn & Moen gage, as the "Steel Wire Gage." In cases where it becomes necessary to distinguish this from the British Imperial standard wire gage, it may be called the "U. S. Steel Wire Gage." This gage applies to all steel wire.

For copper wires and wires of other metals, the gage universally recognized in the United States is the "American Wire Gage," which is also known as the Brown & Sharpe gage. No confusion should arise between the steel wire gage and the American wire gage, because the fields covered by the two gages are distinct and different.

The piano wire gage, designated as the "American Steel & Wire Co.'s Music Wire Gage" is adopted as standard for piano wire upon the recommendation of the United States Bureau of Standards.

The trend of practice in the gaging of materials is increasingly toward the direct specification of dimensions in decimal fractions of an inch without the use of gage numbers. The United States Navy Department in 1911 ordered that all diameters and thicknesses of materials be specified directly in decimal fractions, omitting all reference to gage numbers, and the War Department issued a similar order for wires. This is similar to the practice in Europe where sizes of wire are specified directly by the diameter in millimeters.

The tariff act of 1913 provides for the use of decimal dimensions in measuring wires and rods, but the measurement of steel strips is by gage. As the particular gage was not designated in the tariff act, the Treasury Department in 1914 authorized the use of the American (B. & S.) wire gage. Prior to this the Birmingham wire gage had been employed. The Treasury Department also directed that the measurement of sheets and plates be in decimals of an inch instead of using the standard gage.

Strength of Piano and Plow-steel Wire. — The strength of wire is increased considerably by drawing. So-called piano wire has an ultimate tensile strength of from 300,000 to 340,000 pounds per square inch. The composition of this wire is as follows: Carbon, 0.57 per cent; silicon, 0.09 per cent; sulphur, 0.011 per cent; phosphorus, 0.018 per cent; manganese, 0.425 per cent. This wire is made in sizes ranging from 0.029 to 0.052 inch (music wire gage Nos. 12 to 22 inclusive). So-called "plow-steel" wire has an ultimate tensile strength of 345,000 pounds per square inch for wire 0.093 inch in diameter, and 200,000 pounds per square inch for wire 0.191 inch in diameter. The elongation is only about 1 per cent. The composition is about as follows: Carbon, 0.83 per cent; manganese, 0.59 per cent; silicon, 0.14 per cent; sulphur, 0.01 per cent; phosphorus, nil; copper, 0.03 per cent.

Wire Drawing. — Iron and steel wire from No. 3 to No. 18 Brown & Sharpe wire gage (from 0.229 to 0.040 inch in diameter) is drawn from wire about ¼ inch in diameter through holes in draw plates made of a high-grade tungsten steel. The wire is reduced at each drawing or pass by one number or step in the Brown & Sharpe wire gage scale, and at each drawing operation, the wire passes through but

one hole in the die. In the wire gage scale compiled in 1864 by Messrs. Brown and Sharpe, the diameters of the wires of successive numbers increase according to a geometrical ratio. The diameter of each succeeding number can be found by multiplying the diameter of the preceding number by 1.123, this being the ratio of the geometrical progression. The basic size is No. 36 wire, which is 0.005 inch in diameter.

Fine sizes of iron, steel or alloy-steel wire (between 0.040 and 0.002 inch in diameter) are drawn through diamond dies, which consist of a body made from brass in which the diamond is inserted. The diamond is of the variety known as bort. In the case of these smaller sizes, the wire is passed through a succession of dies (up to ten or twelve) in a single drawing operation. The size of diamond for wire 0.040 inch in diameter is about 3 or 3½ carats, while one-half-carat stones will suffice for dies for drawing wire 0.010 inch in diameter. The life of the diamond die used for drawing steel wire averages only about three days, while for copper wire it may last for six months or a year. The speed at which the wire is drawn appears to have little effect on the life of the die, but the life depends solely on the length of wire passed through it. About 200 pounds of steel wire can be drawn through a No. 32 B. & S. diamond die, before its size is too enlarged for further use. Fifteen pounds of wire only can be drawn through holes from 0.003 to 0.005 inch in diameter. Less than one pound can be drawn through holes smaller than 0.002 inch. When the diamond dies are worn too much, they are re-drilled for a larger gage number. In drilling the diamonds, the average time for enlarging a hole 0.001 inch in diameter is about 1½ hour. For hard music wire, diamonds of comparatively large size are required; thus for holes as small as 0.005 inch in diameter, 2 to 2½ carat diamonds are used.

Copper wire is drawn through dies of chilled cast iron; the reduction for each pass is equal to one number or step on the B. & S. wire gage scale, but the wire passes through a number of successive dies at one operation, as many as ten dies often being mounted in the same wire-drawing machine.

Converting Strength of Wire into Strength in Pounds per Square Inch. — The table given for this conversion has two columns, one headed "Diam. of Wire," and the other "Factor." The strength of the wire of a given diameter should be multiplied by the factor given, in order to obtain the strength per square inch. For example, it is known that a wire 0.035 inch in diameter can sustain a load of 150 pounds before breaking. Then the strength in pounds per square inch of the wire is found as below:

$$150 \times 1040 = 156{,}000 \text{ pounds per square inch.}$$

The factor 1040 is found opposite the diameter 0.035 in the table.

Converting Strength of Wire to Strength per Square Inch

Diameter, Strength and Weight of Steel Wire

The breaking stress of the wire is based on a tensile strength of 100,000 pounds per square inch. For wire of greater or less strength, simply multiply the values in the table by the ratio between actual strength per square inch and 100,000. Example: A No. 15 wire is made of material having a tensile strength of 150,000 pounds per square inch. Then, breaking stress of wire = (150,000 ÷ 100,000) × 407 = 610 pounds.

No. Washburn & Moen, Am. Steel & Wire Co., and Roebling Gage	Diameter, Inches	Area, Sq. Ins.	Breaking Stress of Wire, based on 100,000 Lbs. Stress per Sq. In.	Weight in Pounds		Number of Feet in 2000 Pounds.

It should be noted that the diameters corresponding to the numbers in Stub's steel wire gage (drill rod sizes) are not the same as the diameters that correspond to the same numbers of small drill sizes.

STRENGTH AND PROPERTIES OF WIRE ROPE

Kinds of Wire Rope. — Wire rope is made with different numbers of strands and numbers of wires to the strand, according to the purpose for which it is to be used. Hoisting rope is made of 6 strands with 19 wires to the strand. This type of rope is used for elevators of all kinds, mines, conveyors, derricks, etc. A hoisting rope known as "special flexible" is made of 6 strands with 37 wires each, and one known as "extra flexible" rope is made from 8 strands with 19 wires each. These ropes are used for cranes, counterweights, dredges and similar purposes. The standard transmission or haulage rope is made from 6 strands with 7 wires to the strand. This is much stiffer than the standard hoisting rope and will not bend around as small sheaves. It is, however, better adapted for haulage and transmission purposes, because the wires are larger and do not wear through so quickly. A greater factor of safety than is used for hoisting rope is desirable. A rope made of six strands with 12 wires each, known as "running" rope, is also made.

Wire ropes are usually made with a hemp core or center. Sometimes the hemp center is replaced by a wire strand, which adds from 7 to 10 per cent to the strength of the rope, but as the wear on the center is as great as on the outside strands, but little is gained. The tables of hoisting and haulage rope give the breaking stress in tons for ropes made from different grades of iron and steel. The working stress should, as a rule, not be made greater than one-fifth of the breaking stress. The tables are based on data furnished by the American Steel & Wire Co.

In the regular type of rope, the wires of the strands are twisted in one direction and the strands laid into the rope in the opposite direction. In the Lang's lay rope, both the wires in the strands and the strands in the rope are twisted in the same direction. This rope is more easily untwisted than the regular lay rope and it is more difficult to tuck the strands securely in a splice, but it is well adapted to withstand external wear and grip action.

Galvanized iron wire rope is used for derrick guys and also for stays aboard ship. Galvanized steel wire strands are used for smoke stack guys and similar purposes.

To preserve wire rope, linseed oil should be applied to it. The grooves of cast-iron pulleys and sheaves should be fitted with blocks of hardwood set on end, which are renewed when worn out. This will save wear and increase adhesion. When large sheaves run at high velocity, the grooves should be lined with leather set on end or with India rubber. This is done in the case of sheaves used in the transmission of power between distant points.

Stresses in Wire Ropes Due to Bending. — When wire rope is used over a pulley or sheave there is a longitudinal tension due to the weight suspended by the rope and the weight of the rope itself, and also tension and compression stresses in the part of the rope resting on the pulley due to the bending of the rope. The smaller the sheave the larger are these bending stresses. In order not to increase these stresses too much and cause undue wear in the wire rope, certain *minimum* sizes of sheaves for different sizes of ropes are recommended by the manufacturers of wire ropes and given in the accompanying tables, but whenever a larger diameter can be conveniently used, it is preferable. Various formulas have been deduced for calculating the stresses in wire rope due to the bending over the sheaves. The following, based on a formula used by a prominent wire rope manufacturer, gives safe results:

$$\text{Stress in pounds per square inch} = \frac{Ed}{D} \times 0.45$$

in which E = modulus of elasticity of the material from which the wire is made, about 30,000,000 for steel and 25,000,000 for iron wire;
d = diameter of component wire in inches;
D = diameter of sheave in inches.

In the formula given, the diameter of component wire is used. This diameter is approximately found as follows:

For 6 by 7 rope, $d = 0.106 \times$ diameter of rope;
For 6 by 19 rope, $d = 0.063 \times$ diameter of rope;
For 6 by 37 rope, $d = 0.045 \times$ diameter of rope;
For 8 by 19 rope, $d = 0.050 \times$ diameter of rope.

The total area in square inches of wires of different ropes is given in a following table.

Example: Find the stress due to bending a ½-inch, 6 by 7 extra strong crucible steel-wire rope over a sheave 24 inches in diameter.

$$\text{Stress in pounds per square inch} = \frac{30{,}000{,}000 \times 0.106 \times \frac{1}{2}}{24} \times 0.45 = 29{,}800 \text{ lbs.}$$

Area of rope (from table) = 0.0926 square inch.

Hence, stress due to bending = 2800 pounds, approximately, or 1.4 ton. Breaking stress of rope (from table) = 8.8 tons. Total safe stress = 8.8 ÷ 5 = 1.76 ton. Hence, in this case, the stress due to bending over the sheave is about one-sixth of the total breaking strength of the rope, which, with a factor of safety of 5, leaves a very small margin for the load. This illustrates the need of using as large sheaves as possible.

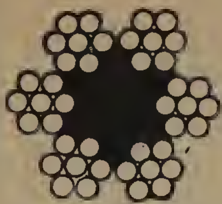
Dimensions and Strength of Haulage Rope



Standard transmission, haulage or standing rope is made of 6 strands and a hemp center, with 7 wires to the strand. The advantage of this rope is that the wires are coarse and resist abrasion and corrosion to the greatest possible extent, but the rope is not highly flexible.

Dimensions and Strength of Standard Hoisting Rope

Standard hoisting rope is made of 6 strands and a hemp center, with 19 wires to the strand. The wires are comparatively small in diameter, and the wire rope, therefore, passes readily around sheaves and drums of moderate size.

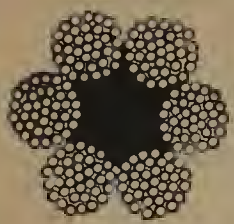
Dimensions and Strength of Special Flexible Hoisting Rope



Special flexible hoisting rope is composed of 6 strands and a hemp center, with 37 wires to the strand. This is a very flexible rope and is used to a great extent on cranes and similar machinery, where the sheaves must necessarily be small in diameter. Hoisting ropes larger than 1¾ inch are usually made of 6 strands with 37 wires each, rather than of 6 strands with 19 wires.

Strength of Wire Rope Drums. — Usually if a drum is designed to be strong enough to resist crushing, it will be strong enough to resist bending also, except in cases of extremely long drums. To be on the safe side, however, the strength should be calculated for both crushing and bending. First consider the calculations to find the crushing stresses. Let:

T = tension in one rope, in pounds;
t = thickness of drum in inches at bottom of groove;
P = pitch of scoring, or distance between grooves in inches;
L = span in inches from center to center of bearings;
D = diameter at the bottom of the groove;
d = inside diameter of drum;
W = total load in pounds;
M_b = bending moment.

Then calculate the total crushing stresses as follows:

$$\text{Section modulus} = Z = 0.0982\left(D^3 - \frac{d^4}{D}\right);\quad M_b = \frac{WL}{4}$$

$$B = \frac{M_b}{Z};\quad C = \frac{T}{Pt}.$$

$$\text{Combined stress} = \sqrt{B^2 + C^2} \qquad (1)$$

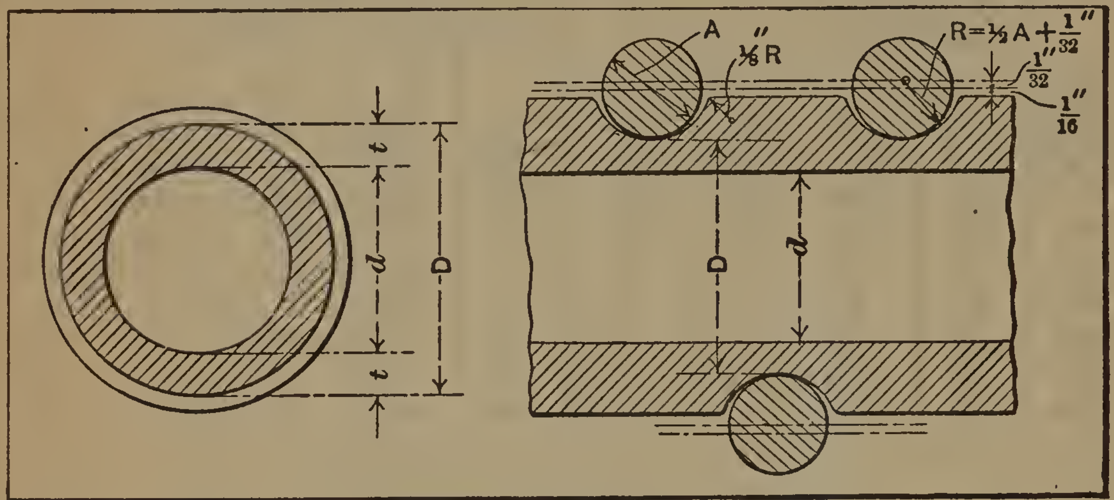
The combined stresses should not exceed 6000 pounds per square inch for cast iron.

To find the strength for bending, let S = safe fiber stress, which should not exceed 3000 pounds per square inch for cast iron.

The diameter of the hole through the drum may then be found from the following formula:

$$d = \sqrt[4]{D^4 - \frac{D \times M_b}{0.0982\,S}} \qquad (2)$$

As an example, assume that on a five-ton crane, two 7/16-inch ropes are used; that the pitch of scoring on the drum is 3/4 inch; and that the distance from center to center of the bearings on the drum is 6 feet 2 inches. The inside diameter of the



drum is 12 inches, and the diameter at the bottom of the grooves, 14 11/16 inches. From the formulas given:

$$Z = 0.0982\left(14.69^3 - \frac{12^4}{14.69}\right) = 172.6;$$

$$M_b = \frac{10{,}000 \times 74}{4} = 185{,}000;$$

$$B = \frac{185{,}000}{172.6} = 1072; \quad C = \frac{5000}{\frac{3}{4} \times 1.34} = 5000.$$

Combined stress $= \sqrt{1072^2 + 5000^2} = 5113$ pounds per square inch.

As this is less than the allowable stress of 6000 pounds per square inch, the drum is safe from crushing.

To determine if the drum will withstand bending, use Formula (2), assuming the diameter at the bottom of the grooves to be 14 11/16 inches and solving for the inside diameter:

$$d = \sqrt[4]{14.69^4 - \frac{14.69 \times 185{,}000}{0.0982 \times 3000}} = 13.9 \text{ inches.}$$

Since the inside diameter is only 12 inches instead of 13.9 inches, it follows that the drum is strong enough for its purpose.

Power Transmission by Wire Rope. — In power transmission by wire rope, a rule frequently followed is to make the minimum diameter of the sheave equal to 100 rope diameters. The radius at the bottom of the groove in the sheaves should always be greater than that of the rope itself, so that the wire rope drives simply through the friction in the bottom of the groove, which is lined with soft rubber, leather, wood or some similar comparatively soft material.

Life of Wire Rope. — The life of wire rope depends in the first place upon the proportions of the diameter of the pulley or sheave to the diameter of the rope.

In general, increasing the diameter of the pulleys by an amount equal to two circumferences of the rope, will double the life of the rope. When ropes are worked over a number of pulleys, the number of bends influences the length of life of the rope. It has also been shown that reverse bends, that is bending a rope in one direction over one pulley and then in the opposite direction over another pulley, has a more detrimental influence on the life of wire rope than two bends in the same direction. Ropes subjected to reverse bends have a life of only half of that of ropes

Transmission of Power by Wire Ropes

(Ropes of 6 strands with hemp core, each strand consisting of 7 wires)

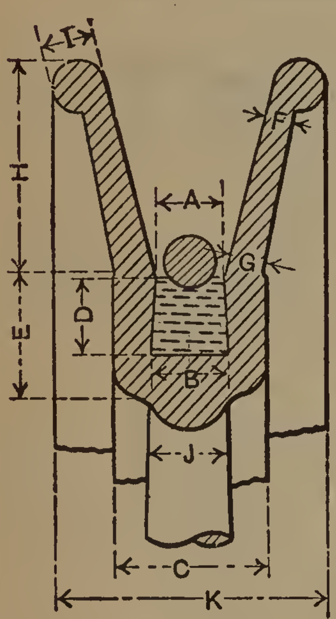
bent in one direction. If it be assumed that a rope making three bends in working, that is, one at the upper drum and one on each side of the lower pulley, as is the arrangement most frequently adopted in crane practice, has a life of 100, then the relative life of ropes with different bends is as follows:

1 single bend, 300; 3 bends in the same direction, 100; 3 bends of which one is a reverse bend, 75; 7 bends, 43; 7 bends of which one is a reverse bend, 37.

This indicates that it is important to increase the diameters of the pulleys when the rope is bent over more than one pulley, in order that the length of life of the rope may be approximately the same when bent over several pulleys, as when subjected to a single bend only. The effect of oiling ropes, upon the length of life, is to increase the life of a given rope by two to three times.

Dimensions of Wire-rope Pulleys for Power Transmission



Arms are made with elliptic cross-section.

Definitions of Wire Rope Terms

Aeroplane Strand: A small 7- or 19-wire galvanized strand made from plow steel or crucible steel wire.

Arc Light Rope: Rope consisting of 9 strands of 4 or 7 galvanized wires and a hemp center.

Bicycle Cord: Small rope consisting of 19 strands of 3 wires each, made from crucible or plow steel.

Cable Laid Rope: A compound laid rope consisting of several ropes or several layers of strands laid together into one rope, as, for instance, 6 by 6 by 7.

Crane Rope: Wire rope consisting of 6 strands of 37 wires around a hemp center.

Crosby Clip: A grooved casting and U-shaped bolt with nuts for fastening wire ropes together.

Dragon Rope: A 6 by 25 triangular flattened strand rope with alternate regular and Lang lay strands, usually made with hemp center.

Elevator Rope: Wire rope usually made of iron and composed of 6 strands of 19 wires each, and a hemp core.

Extra Flexible Hoisting Rope: A rope consisting of 8 strands of 19 wires each with a large hemp center.

Ferry Rope: Rope consisting of 6 strands, 7 wires each, either bright or galvanized.

Flat Rope: A rope consisting of alternate right and left lay rope strands, each rope strand consisting of 4 strands of 7 wires, all sewed together with a number of soft iron sewing wires.

Flattened Strand Rope: A wire rope having non-cylindrical strands, usually of the oval or triangular type; the center wire of each strand is an oval or a triangular wire.

Galvanized Signal Strand: A 7-wire strand made up from single galvanized wire; sometimes made with 19 wires.

Guy Rope: Galvanized rope consisting of 6 strands, 7 wires each, and a hemp core.

Guy Strand: Galvanized 7-wire strand.

Hand Rope: Flexible rope consisting of 6 ropes, each composed of 6 strands, 7 wires each, and 7 hemp cores.

Haulage Rope: Rope usually composed of 6 strands, 7 wires each, and a hemp core.

Hawser: Wire rope usually consisting of 6 strands, 37 wires, and a hemp core, or 6 strands, 24 wires, and 7 hemp cores.

Hoisting Rope: Rope consisting of 6 strands of 19 wires each, with a hemp center.

Lang Lay Rope: Wire rope in which both the wires in the strands and the strands in the rope are twisted in the same direction.

Left Lay Rope: Wire rope, the strands of which form a left-hand helix like a left-hand screw thread.

Left Twist: Same as right lay, and corresponds to a right-hand screw thread.

Lay: The pitch or angle of the helix of the wires or strands of a rope, usually expressed by the ratio of the diameter of the strand or rope to the length required for one complete twist.

Lloyd's Hawser: Wire rope composed of 6 strands, 24 wires, and 7 hemp cores.

Messenger Strand: Seven-wire galvanized strand.

Non-spinning Rope: A wire rope consisting of 18 strands of 7 wires each in two layers; the inner layer consists of 6 strands Lang lay and left lay around a small hemp core, and the outer of 12 strands regular lay, right-hand lay. Will carry a load on a single end without untwisting.

Regular Lay: Strands twisted to the right and rope twisted to the left. Helix of strands takes the direction of a right-hand screw thread.

Reverse Laid Rope: A wire rope with alternate strands right and left lay.

Rheostat Rope: A small rope consisting of 8 strands of 7 wires each.

Right Lay: Known also as regular lay; strands twisted to the right and rope twisted to the left; corresponds to a right-hand screw thread.

Right Twist: Corresponds to left lay, or to a left-hand screw thread.

Running Rope: A flexible rope of 6 strands, 12 wires each, and 7 hemp cores.

Sand Line: A small rope composed of 6 strands of 7 wires each.

Sash Cord: Small rope consisting of 6 strands, 7 wires, and one hemp core; sizes ¼ inch and smaller; plain or galvanized.

Seizing Strand: Small galvanized 7-wire strand usually made in sizes ⅛ inch diameter and smaller.

Signal Strand: Usually consists of a 7-wire galvanized strand.

Special Flexible Hoisting Rope: A wire rope consisting of 6 strands, of 37 wires each, and a hemp core.

Standing Rope: Another term applied to galvanized guy rope which consists of 6 strands, 7 wires, and a hemp core.

Tiller Rope: Rope consisting of 6 ropes of 6 strands, each of 7 wires, and 7 hemp cores.

Towing Hawser: A large flexible wire rope made of galvanized wires. Usual construction, 6 strands of 37 wires each, or 6 strands of 24 wires each.

Transmission Rope: Rope composed of 6 strands, 7 wires each, and a hemp core.

Universal Lay: Another name for Lang lay.

SPRINGS

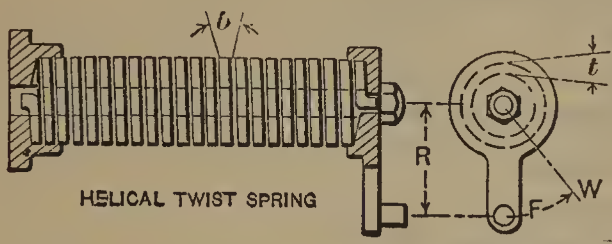
Formulas for Strength and Deflection of Springs

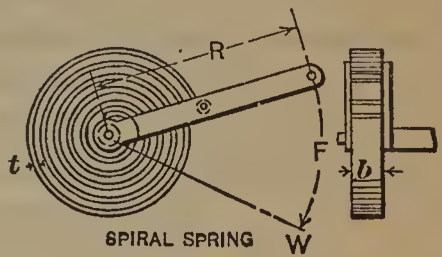
W = safe load, pull or pressure in pounds;
F = deflection at point of application of load, in inches;
S = safe tensile strength of the material, in pounds per square inch;
E = modulus of elasticity = 30,000,000 for steel.

Type of Spring	W, Safe Load	F, Deflection
	$\frac{Sbt^2}{6l}$	$\frac{4Wl^3}{Ebt^3} = \frac{2Sl^2}{3Et}$
	$\frac{Sbt^2}{6l}$	$\frac{6Wl^3}{Ebt^3} = \frac{Sl^2}{Et}$
	$\frac{SNbt^2}{6l}$ in which N = number of leaves.	$\frac{6Wl^3}{ENbt^3} = \frac{Sl^2}{Et}$ in which N = number of leaves.
	$\frac{SNbt^2}{3l}$ in which N = number of leaves in one-half of the spring; t = thickness of leaf.	$\frac{6Wl^3}{ENbt^3} = \frac{2Sl^2}{Et}$ in which N = number of leaves in one-half of the spring; t = thickness of leaf.
	$\frac{Sbt^2}{6p}$	$\frac{18Wp^3}{Ebt^3} = \frac{3Sp^2}{Et}$

Formulas for Strength and Deflection of Springs

W = safe load, pull or pressure in pounds;
F = deflection at point of application of load, in inches;
S = safe tensile strength of the material in pounds per square inch (in the torsion and helical compression and extension springs, S = torsional or shearing stress); E = modulus of elasticity = 30,000,000 for steel; G = torsional modulus of elasticity = 12,600,000 for steel.





W = safe load.

For flat or square steel: $W = \dfrac{Sbt^2}{6R}$ For round steel (d = diam. of rod): $W = \dfrac{Sd^3}{10R}$

F = deflection.

For flat or square steel (l = length of the rod or uncoiled spring): $F = \dfrac{12\,WlR^2}{Ebt^3} = \dfrac{2\,SlR}{Et}$

For round steel (d = diameter of rod; l = length, as above): $F = \dfrac{20\,WlR^2}{Ed^4} = \dfrac{2\,SlR}{Ed}$

If U = deflection expressed in revolutions of the lever:

$U = \dfrac{Sl}{3\,Et}$ for flat and square, and $\dfrac{Sl}{3\,Ed}$ for round steel, approx.

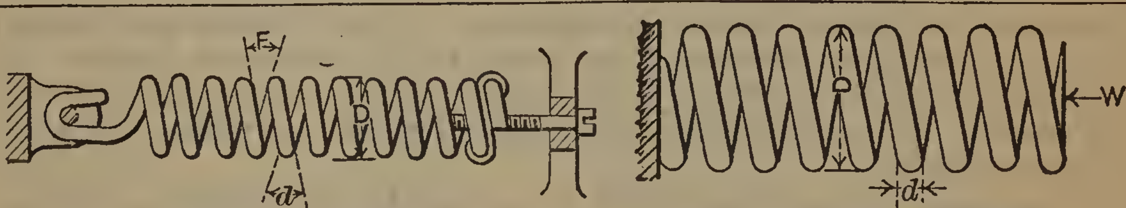
W = safe load.

For square rod: $W = \dfrac{Sd^3}{4R}$ approx.

For round rod: $W = \dfrac{Sd^3}{5R}$

F = deflection.

For square rod: $F = \dfrac{6\,WR^2l}{Gd^4} = 1.5\dfrac{SlR}{Gd}$ For round rod: $F = \dfrac{10\,WR^2l}{Gd^4} = \dfrac{2\,SlR}{Gd}$



W = safe load.

For square rod (d = side of square): $W = 0.47\dfrac{Sd^3}{D-d}$ approx.

For round rod: $W = 0.4\dfrac{Sd^3}{D-d}$

F = deflection of one coil.

For square rod (d = side of square): $F = \dfrac{4.7\,W\,(D-d)^3}{Gd^4} = \dfrac{2.2\,S\,(D-d)^2}{Gd}$

For round rod: $F = \dfrac{8\,W\,(D-d)^3}{Gd^4} = \dfrac{3.14\,S\,(D-d)^2}{Gd}$

Maximum Safe Stresses in Coil Springs. — The following values may be used for the torsional or shearing stresses in coil springs made from a good grade of steel. Assume the ratio of the mean diameter of the spring to the diameter of the bar to equal R; then:

For bars below 3/8 inch diameter:

$R = 3$ $S = 112{,}000$ pounds per square inch.
$R = 8$ $S = 85{,}000$ pounds per square inch.

For bars 7/16 to 3/4 inch in diameter:

$R = 3$ $S = 110{,}000$ pounds per square inch.
$R = 8$ $S = 80{,}000$ pounds per square inch.

For bars from 13/16 to 1 1/4 inch in diameter:

$R = 3$ $S = 105{,}000$ pounds per square inch.
$R = 8$ $S = 75{,}000$ pounds per square inch.

For bars over 1 1/4 inch in diameter a stress of more than 100,000 should not be used. Where a spring is subjected to sudden shocks, a smaller value of S is necessary.

These values are applicable to compression springs with open coils. Experience has shown that in close-coiled springs and extension springs the safe value of the stress per square inch, S, is only about two-thirds of that for open-coiled compression springs of the same dimensions. The safe torsional or shearing strength for spring brass and phosphor-bronze may be taken as 25,000 pounds per square inch. The torsional modulus of elasticity may be taken as 6,000,000 for spring brass and phosphor-bronze, and 12,600,000 for steel.

An analysis of spring steel frequently used, and known as the P.R.R. analysis, is as follows: Carbon 1.0 per cent (not under 0.90 per cent); phosphorus, 0.05 per cent (not over 0.07 per cent); manganese, 0.25 per cent (not over 0.50 per cent); silicon, not over 0.10 per cent; sulphur, not over 0.03 per cent.

The best proportions for coil springs is to use an outside diameter of the spring equal to from five to eight times the diameter of wire or bar from which the spring is made; under no circumstances should the outside diameter be made less than four times the diameter of the wire. The effective number of coils in a compression spring may be considered as 2 less than the actual number, owing to the squared ends of the spring. Springs of small diameter may be safely subjected to a higher unit stress than those of large diameter.

Formulas for Helical Round Bar Springs. — In the following are tabulated all formulas relating to helical round bar springs that are required in practice. In each case, the general formula is given, and, below, the formula is simplified for steel springs. All dimensions are in inches and all weights and stresses in pounds. In the formulas:

d = diameter of bar from which spring is made;
D = mean diameter of coil;
F = total deflection under load P; the deflection F_1 under any other load is proportionate to this deflection;
h = solid height of spring;
H = free height of spring;
L = length of bar from which spring is made;
W = weight of bar, or spring;
w = weight of material per cubic inch;
P = carrying capacity of spring or weight that will compress the spring solidly;
S = maximum fiber stress, assumed as 80,000 pounds per square inch for steel;
G = torsional modulus of elasticity, assumed as 12,600,000 for steel.

Formulas for Helical Round Bar Springs — 1

(For notation used in formulas, see previous page)

To be Found	Formulas	Examples
P, maximum carrying capacity	$P = \frac{GFd^5}{8\,hD^3}$ $= \frac{3.14\,Sd^3}{8\,D}$ or, for steel springs: $P = 1{,}575{,}000\,\frac{Fd^5}{hD^3}$ $= 31{,}400\,\frac{d^3}{D}$	Steel spring, outside diameter $= 2\frac{7}{8}$ inches; Diameter of bar $= \frac{1}{2}$ inch; Free height $= 14\frac{1}{2}$ inches; Solid height $= 10$ inches. $P = 1{,}575{,}000 \times \frac{4.5 \times 0.5^5}{10 \times 2.375^3}$ $= 1650$ pounds.
F, total deflection under load P	$F = \frac{3.14\,ShD^2}{Gd^2} = H - h$ $= \frac{H}{1 + \frac{Gd^2}{3.14\,SD^2}}$ or, for steel springs: $F = 0.02\,h\left(\frac{D}{d}\right)^2$ $= \frac{H}{1 + 50.1\left(\frac{d}{D}\right)^2}$	Steel spring, outside diameter $= 4\frac{1}{4}$ inches; Diameter of bar $= \frac{3}{4}$ inch; Solid height $= 10$ inches. $F = 0.02 \times 10 \times \left(\frac{3\frac{1}{2}}{\frac{3}{4}}\right)^2 = 4.34$ inches. Outside diameter $= 5\frac{1}{2}$ inches; Diameter of bar $= 1\frac{3}{8}$ inch; Free height $= 11\frac{3}{4}$ inches. $F = \frac{11\frac{3}{4}}{1 + 50.1 \times \left(\frac{1\frac{3}{8}}{4\frac{1}{8}}\right)^2} = 1\frac{3}{4}$ inch.
F_1, deflection under any load P_1 less than P	$F_1 = \frac{8\,P_1hD^3}{Gd^5}$ or, for steel springs: $F_1 = 0.0000006\,\frac{P_1hD^3}{d^5}$	Steel spring, outside diameter $= 4\frac{1}{4}$ inches; Diameter of bar $= \frac{3}{4}$ inch; Solid height $= 10$ inches; Load $P_1 = 1000$ pounds. $F_1 = 0.0000006\,\frac{1000 \times 10 \times (3\frac{1}{2})^3}{(\frac{3}{4})^5}$ $= 1.08$ inch.
S, maximum fiber stress	$S = \frac{8\,DP}{3.14\,d^3}$ $= \frac{GF}{3.14\,h}\left(\frac{d}{D}\right)^2$ or, for steel springs: $S = 2.55\,\frac{DP}{d^3}$ $= 4{,}000{,}000\,\frac{F}{h}\left(\frac{d}{D}\right)^2$	Steel spring, outside diameter $= 4\frac{1}{2}$ inches; Diameter of bar $= \frac{1}{2}$ inch; Free height $= 22\frac{3}{4}$ inches; Solid height $= 10$ inches. $S = 4{,}000{,}000 \times \frac{12.75}{10} \times \left(\frac{0.5}{4}\right)^2$ $= 80{,}000$ pounds, about.
H, free height	$H = h + \frac{3.14\,Sh}{G}\left(\frac{D}{d}\right)^2$ $= h + F$ or, for steel springs: $H = h + 0.02\,h\left(\frac{D}{d}\right)^2$	Steel spring, outside diameter $= 7\frac{1}{8}$ inches; Diameter of bar $= 1\frac{1}{8}$ inch; Solid height $= 10$ inches. $H = 10 + 0.02 \times 10 \times \left(\frac{6}{1\frac{1}{8}}\right)^2$ $= 15.67$ inches.

Formulas for Helical Round Bar Springs — 2

To be Found	Formulas	Examples
h, solid height	$h = \dfrac{H}{1 + \dfrac{3.14S}{G}\left(\dfrac{D}{d}\right)^2}$ or, for steel springs: $h = \dfrac{H}{1 + 0.02\left(\dfrac{D}{d}\right)^2}$	Steel spring, outside diameter = 6 inches; Diameter of bar = $1\frac{1}{8}$ inch; Free height = $13\frac{3}{4}$ inches. $h = \dfrac{13.75}{1 + 0.02\left(\dfrac{4\frac{7}{8}}{1\frac{1}{8}}\right)^2} = 10$ inches.
h, solid height	Let P_1 = any load less than P; h_1 = height under load P_1. $h = \dfrac{h_1}{1 + \dfrac{3.14S}{G}\left(\dfrac{P - P_1}{P}\right)\left(\dfrac{D}{d}\right)^2}$ or, for steel springs: $h = \dfrac{h_1}{1 + 0.02\left(\dfrac{P - P_1}{P}\right)\left(\dfrac{D}{d}\right)^2}$	Steel spring, outside diameter = $5\frac{1}{2}$ inches; Diameter of bar = $\frac{3}{4}$ inch; Free height = 18 inches. What solid height is required for carrying 1395 pounds at 14 inches? P = 2790 pounds by formula $P = \dfrac{3.14\,Sd^3}{8D}$ Then, $h = \dfrac{14}{1 + 0.02\left(\dfrac{2790 - 1395}{2790}\right)\left(\dfrac{4\frac{3}{4}}{\frac{3}{4}}\right)^2} = 10$ inches
L, length of bar	$L = \dfrac{3.14\,hD}{d}$ $= \dfrac{H}{\dfrac{SD}{Gd} + 0.32\dfrac{d}{D}}$ or, for steel springs: $L = \dfrac{H}{0.0063\dfrac{D}{d} + 0.32\dfrac{d}{D}}$	Steel spring, outside diameter = $4\frac{3}{8}$ inches; Diameter of bar = $\frac{7}{16}$ inch; Solid height = 10 inches. $L = \dfrac{3.14 \times 10 \times 3\frac{15}{16}}{\frac{7}{16}}$ = 282.7 inches.
W, weight of spring	$W = \dfrac{3.14^2\,dDhw}{4}$ $= \dfrac{2\,GwPF}{S^2}$ or, for steel springs: $W = 0.7\,dDh$ $= 0.0011\,PF$	Steel spring, outside diameter = $3\frac{3}{4}$ inches; Diameter of bar = $\frac{15}{16}$ inch; Solid height = 10 inches. $W = 0.7 \times \frac{15}{16} \times 2\frac{13}{16} \times 10$ = 18.3 pounds.
G, torsional modulus of elasticity	$G = \dfrac{3.14\,Sh}{F}\left(\dfrac{D}{d}\right)^2$ $= \dfrac{8\,PhD^3}{Fd^5}$ or, for steel springs: $G = 251{,}000\,\dfrac{h}{F}\left(\dfrac{D}{d}\right)^2$	Steel spring, outside diameter = $4\frac{7}{8}$ inches; Diameter of bar = $\frac{11}{16}$ inch; Load = 1219 pounds; Deflection = 3.7 inches; Solid height = 10 inches. $G = \dfrac{8 \times 1219 \times 10 \times (4\frac{3}{16})^3}{3.7 \times (\frac{11}{16})^5}$ = 12,600,000.

Formulas for Helical Rectangular Bar Springs

Notation: D, F, F_1, h, H, L, W, w, P, S and G denote the same quantities as for helical round bar springs; see the next preceding pages; b = width of rectangular bar; t = height of rectangular bar (parallel to axis of spring). For square bar springs $b = t$ = side of square. — These formulas give approximate results, and should be used only when the difference between b and t is not very great.

To be Found	Formulas	To be Found	Formulas
P, maximum carrying capacity	$P = \frac{Sbt\sqrt{t^2+b^2}}{3D} = \frac{GFbt^2(t^2+b^2)}{9.4\,hD^3}$ or, for steel springs: $P = \frac{26{,}700\,bt\sqrt{t^2+b^2}}{D} = \frac{1{,}337{,}000\,Fbt^2(t^2+b^2)}{hD^3}$	h, solid height	$h = \frac{H}{1+\frac{3.14\,SD^2}{Gt\sqrt{t^2+b^2}}}$ or, for steel springs: $h = \frac{H}{1+0.02\frac{D^2}{t\sqrt{t^2+b^2}}}$
F, total deflection under load P	$F = \frac{3.14\,ShD^2}{Gt\sqrt{t^2+b^2}} = \frac{H}{1+\frac{Gt\sqrt{t^2+b^2}}{3.14\,SD^2}}$ or, for steel springs: $F = 0.02\frac{hD^2}{t\sqrt{t^2+b^2}} = \frac{H}{1+50.1\frac{t\sqrt{t^2+b^2}}{D^2}}$	L, length of bar	$L = \frac{3.14\,Dh}{t} = \frac{H}{\frac{SD}{G\sqrt{t^2+b^2}}+0.32\frac{t}{D}}$ or, for steel springs: $L = \frac{H}{0.0063\frac{D}{\sqrt{t^2+b^2}}+0.32\frac{t}{D}}$
F_1, deflection under any load P_1 less than P	$F_1 = \frac{9.4\,hD^3P_1}{Gbt^2(t^2+b^2)}$ or, for steel springs: $F_1 = 0.00000075\frac{hD^3P_1}{bt^2(t^2+b^2)}$	H, free height	$H = h + \frac{3.14\,hSD^2}{Gt\sqrt{t^2+b^2}}$ or, for steel springs: $H = h + 0.02\frac{hD^2}{t\sqrt{t^2+b^2}}$
S, maximum fiber stress	$S = \frac{3\,DP}{bt\sqrt{t^2+b^2}} = \frac{GFt\sqrt{t^2+b^2}}{3.14\,hD^2}$ or, for steel springs: $S = 4{,}000{,}000\frac{Ft\sqrt{t^2+b^2}}{hD^2}$	W, weight of spring	$W = 3.14\,bDhw = \frac{3\,GwPF}{S^2}$ or, for steel springs: $W = 0.89\,bDh = 0.0017\,PF.$

Conical Coil Springs. — All dimensions in inches, all weights in pounds. Let:

F = deflection or extension, under load P;
D_1 = mean diameter of largest coil;
D_2 = mean diameter of smallest coil;
p = average horizontal pitch of coils;
d = diameter of bar or wire from which coil is made;
P = capacity of spring, or weight that will compress the spring solidly;
l = length of bar in spring;
W = weight of spring;
h = solid height of spring, assumed to equal $d \times$ number of coils.

In the following formulas the allowable stress is assumed as 80,000 pounds per square inch, and the modulus of torsional elasticity as 12,600,000.

Extension conical springs:

$$F = 0.00249 \frac{D_1^4 - D_2^4}{pdD_1} \qquad P = 31{,}400 \frac{d^3}{D_1}$$

Compression conical springs:

$$F = 0.00332 \frac{D_1^3 - D_2^3}{pd} \qquad P = 31{,}400 \frac{d^3}{D_2}$$

For all conical springs:

$$l = 1.571 \frac{h}{d}(D_1 + D_2) \qquad W = 0.35\, dh\,(D_1 + D_2)$$

If P_x is any load not exceeding P, then the corresponding deflection of a conical extension spring is:

$$F_x = \frac{P_x (D_1^4 - D_2^4)}{Gpd^4}$$

In a compression spring, the formula for the deflection under any load is the same as that just given for P_x in an extension spring, provided the load P_x is not greater than the capacity of the largest coil. If, in a compression spring, load P_x is greater than the capacity of the largest coil, but less than the capacity P of the whole spring, then some coils will be compressed down solidly, while the remainder will not be fully compressed.

Example: — Compression spring, $D_1 = 4\frac{9}{16}$ inches; $D_2 = 3\frac{9}{16}$ inches; $d = 1\frac{1}{16}$ inch; $h = 7\frac{1}{16}$ inches.

Then number of coils, $N = \frac{h}{d} = 6.65$; $\frac{D_1 - D_2}{2} = 0.5$; $p = \frac{D_1 - D_2}{2N} = 0.075$.

$$F = 0.00332 \frac{(4\frac{9}{16})^3 - (3\frac{9}{16})^3}{0.075 \times 1\frac{1}{16}} = 2\frac{1}{16} \text{ inches, approximately.}$$

Free height $= 7\frac{1}{16} + 2\frac{1}{16} = 9\frac{1}{8}$ inches.

Example: — Same spring in extension.

$$F = 0.00249 \frac{(4\frac{9}{16})^4 - (3\frac{9}{16})^4}{0.075 \times 1\frac{1}{16} \times 4\frac{9}{16}} = 1\frac{7}{8} \text{ inch, approximately.}$$

H (extended height) $= 7\frac{1}{16} + 1\frac{7}{8} = 8\frac{15}{16}$ inches.

The free height for the compression type is greater than the possible extended length for the extension type. This is because sufficient load to fully stress the smaller or stronger coils cannot be applied without distorting the extension spring, whereas the coils may all be stressed to maximum stress in the compression type, the closing of the coils solidly together protecting the spring from over-stress.

Materials Used for Springs. — Steel containing about one per cent carbon and comparatively free from phosphorus and sulphur, generally known as spring steel, is ordinarily used for springs.

For small springs, music wire is used to a great extent and is the best material obtainable for this purpose. It is especially recommended for devices where the spring is compressed frequently and suddenly. Vanadium steel has recently come into use to a considerable extent for springs. The addition of a small percentage of vanadium to steel increases the elasticity of the material, but the cost of springs made from this material is considerably higher.

Brass and phosphor-bronze should be used for springs that must resist moisture These springs, however, are much more expensive than steel springs, both on account of the higher cost of the material, and because the permissible stress is less, thus making larger sizes of these springs necessary for the same capacity.

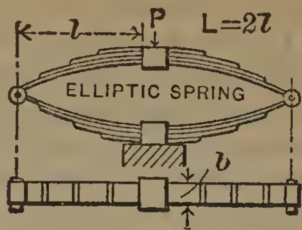
Composition of Phosphor-bronze. — One of the principal uses of phosphor-bronze is for springs. A good mixture for this purpose is as follows: Copper, 95 per cent by weight; tin, 4.5 per cent; five-per cent phosphor-tin, 0.5 per cent. — For phosphor-bronze of the highest possible strength, the following mixture is recommended: Copper, 90 per cent; tin, 9 per cent; five-per cent phosphor-tin, 1 per cent. The alloy made according to this formula is poured into ingots and then re-melted and poured into sand castings. The re-melting increases the strength. — For ordinary work, when a medium strength is required, and when the scrap is used over and over again, the following mixture is recommended: Copper, 90 per cent; tin, 8 per cent; five-per cent phosphor-tin, 2 per cent. — For phosphor-bronze bearings, the following alloy is used: Copper, 80 per cent; tin, 8 per cent; lead, 10 per cent; five-per cent phosphor-tin, 2 per cent. Zinc should never be present.

Factor of Safety in Springs Frequently Compressed. — When a spring acts only occasionally it can be safely designed to carry a load which causes a fiber stress nearly equal to the elastic limit of the spring, but when the compressions or extensions are frequent, a larger factor of safety must be used. A valve spring in an automobile motor, for example, which operates, say, 200 times a minute, should have a factor of safety of at least 4. In other words, a spring made of 1/8-inch wire, which ordinarily could be designed for a torsional stress of 100,000 pounds per square inch, should be designed to work at a stress not over 25,000 pounds per square inch when used in service of the kind mentioned.

High-class springs, such as valve springs, should have the ends squared and ground at right angles to their axis; the outside diameter should be at least one-third of the length, and it should be supported its entire length, unless it is very short, in order to prevent buckling, which introduces bending and twisting strains. High-class valve springs when placed on end on a flat plate should not vary more than 1/2 degree from the perpendicular to the plate. These springs should be protected from rusting by a good coat of japan, baked on, or by electro-galvanizing.

Elliptic Springs. — Elliptic springs are used to a great extent in automobile design, because this class of spring lends itself more readily to easy vibration, as well as to a better general design of the machine. It is possible to support a given load on a narrow-leafed elliptic spring, where there would not be room enough for a helical spring. Automobile springs call for a higher grade of steel than the ordinary spring steel. Various grades of high-carbon, nickel, chromium and vanadium steels are used. Certain alloys of the vanadium class have an elastic limit of from 180,000 to 225,000 pounds per square inch, according to the heat treatment given, and appear to be the most ideal steels for elliptic springs yet produced. Data giving the physical characteristics of various alloy steels when subjected to specific heat treatment will be found in the section "Application and Heat Treatment of S. A. E. Carbon and Alloy Steels."

Formulas for Elliptic Springs



S = fiber stress, assumed as 80,000 pounds per square inch for steel;
E = modulus of elasticity = 25,400,000;
P = maximum carrying capacity of spring;
F = deflection of spring under load P; the deflection under any load less than P is directly proportional to the deflection under full load;
n = number of plates or leaves in half-elliptic spring, or one-half total number of leaves in full-elliptic spring;
b = width of plates; h = thickness of plates; $L = 2\,l$ = effective span;
r = ratio of number of full length leaves to total number of leaves.

Type of Spring	To be Found	Formulas	Examples
Full-elliptic, with all leaves graduated	P	$P = \frac{2\,Snbh^2}{3\,L}$ or, for steel springs: $P = 53{,}000\,nbh^2 \div L$	Steel spring, number of leaves in one-half of spring = 5; Width of plates = 2 inches; Thickness of plates = $\frac{1}{4}$ inch; Effective span, $L = 33$ inches. Find safe load. $P = [53{,}000 \times 5 \times 2 \times (\frac{1}{4})^2] \div 33$ = 1000 pounds, approx.
	F	$F = \frac{SL^2}{2\,Eh}$ or, for steel springs: $F = 0.0016\,L^2 \div h$	
Full-elliptic, with portion of leaves graduated	P	$P = \frac{2\,Snbh^2}{3\,L}$ or, for steel springs: $P = 53{,}000\,nbh^2 \div L$	Same spring as above, with two leaves in each half extending full length of span. Find deflection. Here $r = 2 \div 5 = 0.4$. $F = 0.0031\,\frac{33^2}{(2 + 0.4)\,\frac{1}{4}}$ = 5.625 inches.
	F	$F = \frac{1}{2 + r} \times \frac{SL^2}{Eh}$ or, for steel springs: $F = 0.0031\,\frac{L^2}{(2 + r)\,h}$	
Half-elliptic, with all leaves graduated	P	$P = \frac{2\,Snbh^2}{3\,L}$ or, for steel springs: $P = 53{,}000\,nbh^2 \div L$	Same spring as above, but half-elliptic. Find deflection, if all leaves are fully graduated. $F = (0.00079 \times 33^2) \div \frac{1}{4}$ = 3.44 inches.
	F	$F = \frac{SL^2}{4\,Eh}$ or, for steel springs: $F = 0.00079\,L^2 \div h$	
Half-elliptic, with portion of leaves graduated	P	$P = \frac{2\,Snbh^2}{3\,L}$ or, for steel springs: $P = 53{,}000\,nbh^2 \div L$	Same spring as above, half-elliptic, with three leaves extending full length of span. Find deflection. $F = 0.0016\,\frac{33^2}{(2 + 0.6)\,\frac{1}{4}}$ = 2.68 inches.
	F	$F = \frac{1}{2\,(2 + r)} \times \frac{SL^2}{Eh}$ or, for steel springs: $F = 0.0016\,\frac{L^2}{(2 + r)\,h}$	

Simplified Elliptic Spring Calculations. — The accompanying "Semi-elliptic Spring Table," which is based on a modulus of elasticity of 25,400,000, and a fiber stress, under maximum load, of 80,000 pounds per square inch, has been prepared to facilitate the calculation of semi- or half-elliptic springs when all the leaves are fully graduated. The safe load on one leaf, one inch wide, is found by dividing the constant given in Column "P_u" by the net length or net span L (see illustration in table on preceding page for method of measuring $L = 2\,l$). The corresponding deflection is found by multiplying the constant given in the Column "F_u" by the square of the net length L.

Example: — What is the safe load on a semi- or half-elliptic fully graduated spring of five leaves, if made of ¼- by 2-inch steel; length between end bearings, 36 inches; band or seat, 3 inches?

Net length = 36 − 3 = 33 inches.

$$\text{Load on one leaf, one inch wide} = \frac{3333}{33} = 101.01 \text{ pounds.}$$

Load on one leaf two inches wide = 2 × 101.01 = 202.02 pounds.
Load on five two-inch leaves = 5 × 202.02 = 1010.1 pounds.
Corresponding deflection is:

$$0.00315 \times (33)^2 = 3.43 \text{ inches.}$$

Semi-Elliptic Spring Table

P_u = safe load for one leaf, 1 inch wide, having a net length of 1 inch. F_u is the corresponding deflection. Table is directly applicable only when all leaves are fully graduated.

Thickness of Leaf	P_u	F_u	Thickness of Leaf	P_u	F_u	Thickness of Leaf	P_u	F_u

While the table is prepared for semi-elliptic springs with all leaves fully graduated, it can be used for other types of elliptic springs, if the values in the table are multiplied by certain factors.

Semi-elliptic springs with portions of the leaves graduated. — The load P remains the same as for a spring with all leaves graduated. To find the deflection, multiply the values in the table by $\frac{2}{2+r} \times L^2$, where r = the ratio of the number of full length leaves to the total number of leaves.

Full-elliptic springs with all leaves graduated. — P remains the same as for a semi-elliptic spring. To find the deflection, multiply the values in the table by $2\,L^2$.

Full-elliptic springs with a portion of the leaves graduated. — The load P remains the same as before, but to find the deflection, the values in the table must be multiplied by $\frac{4}{2+r} \times L^2$, in which r is the ratio of the number of full length leaves to the total number of leaves in one-half of the spring.

Example: — Find the load and deflection of a full-elliptic fully graduated spring having four leaves in each half; thickness of leaf = ¼ inch; effective length L = 30 inches; width of leaves, 1¾ inch. Then maximum safe load equals:

$$P = 4 \times 1\tfrac{3}{4} \times \frac{3333}{30} = 778 \text{ pounds.}$$

The deflection equals:

$$F = 2 \times 30^2 \times 0.00315 = 5.67 \text{ inches.}$$

Example: — Find the thickness and number of leaves to be used in a fully graduated full-elliptic spring which has to support 780 pounds with a deflection not exceeding 5¾ inches; the effective length L of the spring is 30 inches and the width, 1¾ inch.

The deflection equals $2\,L^2 \times$ the constant F_u in the table; hence, $F = 2\,F_uL^2$ or:

$$F_u = F \div 2\,L^2 = 5.75 \div 1800 = 0.0032 \text{ inch.}$$

The thickness of steel which corresponds to this value F_u is ¼ inch. To find the load on one leaf, 1 inch wide, the value P_u in the table is divided by the net length of the spring. Hence, load equals 3333 ÷ 30 = 111 pounds. The load on one leaf, 1¾ inch wide, is then 111 × 1.75 = 194.25 pounds. The number of leaves required is, then, equal to the total load divided by the load on one leaf, or the required number equals 780 ÷ 194.25 = 4 leaves.

The formulas given for the calculation of elliptic springs make no allowance for variation in the thickness of different leaves in a spring. When such springs are used, the deflection of the different leaves will not be uniform, and such springs must be calculated by a general formula based upon a combination of different cantilevers, thus making allowance for the different depths of the leaves. There is nothing to be gained, however, by using leaves of different thicknesses, and springs composed of leaves of but one thickness can be designed to meet all requirements.

Results obtained from fully graduated full-elliptic springs indicate that the friction between the leaves is not great enough to seriously affect the bending action. The formulas on the preceding pages give results that agree very closely with actual conditions as determined by experiments.

Tables of Powers of Numbers for Spring Calculations. — The third, fourth and fifth powers of numbers frequently are met with in spring calculations. Tables of cubes, fourth powers and fifth powers of fractional sizes, such as are likely to be used for springs, are, therefore, given in the following pages.

Fifth Powers of Numbers

Number	Fifth Power	Number	Fifth Power	Number	Fifth Power	Number	Fifth Power

Helical Spring Tables. — These tables give the capacity of springs or the load which will compress springs solidly, and also values for determining the free height when the solid height is known. The tables are based upon the assumption that the torsional fiber stress, when the spring is compressed down solidly, is 80,000 pounds per square inch. In the tables:

D = outside diameter of coil in inches;
R = mean radius of coil in inches;
P = load when spring is compressed down solidly, in pounds;
H = free height of spring in inches;
h = solid height of spring in inches.

The use of the tables is best illustrated by an example. Find the free height and capacity of a spring made from 1¹⁄₁₆-inch steel bar, 4 inches in outside diameter, and 8 inches solid height. From the "Helical Spring Tables," we find that the capacity of this spring is 3100 pounds, and that the free height is 11.71 inches.

Find the free height of the same spring, if the solid height were 14 inches. In this case take 10 times the value of H as found in Column "1" and add to it the value of H as found in Column "4." Thus, $14.6 + 5.86 = 20.46$ inches.

Elliptic Spring Tables. — The "Elliptic Spring Tables" give the maximum static load and the deflection under this load when the length or span of the spring, the number of leaves, and the width and thickness of the leaves are known. The maximum static load as given in these tables induces a fiber strain of 80,000 pounds per square inch in the leaves, and the oscillations may increase this to 100,000 pounds. The successive leaves are supposed to be regularly shortened or "graduated" in the full-elliptic spring. In the half-elliptic spring it is assumed that one-quarter of the whole number of leaves extend to the end of the spring and that the remainder are graduated. In the tables:

L = span, or length of spring in inches, not including band.
F = deflection under load P in inches for both half- and full-elliptic springs;
P = maximum static load in pounds;
N = number of leaves in the half-elliptic spring, or number of leaves in one of the halves of a full-elliptic spring;
B = width of leaves in inches.

As an example of the use of the tables, find the maximum load and deflection of a half-elliptic spring having 5 leaves made of ⅜ by 4-inch steel and having a length of 30 inches. By referring to the tables, the deflection is found to equal 1.47 inch under a maximum static load. This load is found as follows: $N \times B = 5 \times 4 = 20$. Then the maximum static load equals 10 times the value found in the column headed "2," or $10 \times 500 = 5000$ pounds.

The table can also be used for finding the maximum static load and the deflection if all the leaves of the spring extend the full length of the span. The maximum load in this case will be the same as when the leaves are graduated, but the deflection will be less. For full-elliptic springs it will be two-thirds of the amounts given in the column under "F" headed "Full." For half-elliptic springs it will be one-third of the amounts given in the column headed "Full." As an example, find the maximum static load and the deflection of a full-elliptic spring having 7 leaves in each half, 4 inches wide, all extending the full length of the span. The leaves are made of ⅜-inch thick steel and the span is 30 inches. From the table the deflection is found as follows: $3.20 \times \frac{2}{3} = 2.14$ inches. The value of $N \times B = 4 \times 7 = 28$. The maximum load, then, equals:

The value in column "2" × 10	= 5000
The value in column "8"	= 2000
Maximum load	= 7000 pounds

Helical Spring Tables

Values of *P* for Varying Values of $N \times B$ (columns 1–9)

Helical Spring Tables Covering Steel Wire Gage Sizes. — The accompanying tables "Maximum Loads in Pounds and Corresponding Compressions per Coil in Inches of Helical Round Bar Springs," cover the commercial sizes of helical steel springs. These tables are calculated for a fiber stress of 100,000 pounds per square inch, with a torsional modulus of elasticity of 11,520,000, and apply to high-grade spring wire. The tables cover springs made from wire sizes varying from No. 26 (0.0181 inch) *steel wire gage* (which is the same as the American Steel & Wire Co.'s gage, the Washburn & Moen gage and the Roebling gage) to wire 5/8 inch in diameter.

Values Given in Helical Spring Tables. — The tables give in the two extreme left-hand columns the size of the wire from which the spring is made by gage number (steel wire gage) and in decimals, respectively. Along the top of the tables is given the mean or pitch diameter of the spring. To find the values relating to any one spring, first locate in the left-hand column the size of wire from which the spring is made, and then follow the horizontal line from this size to the column headed by the mean diameter of the spring. For example, assume that the values for a spring made from No. 10 gage wire, having a mean or pitch diameter of 1 1/8 inch, are to be found. The No. 10 wire is located in the left-hand column, and then the lines applying to this size of wire are followed horizontally until the column headed 1 1/8 is reached. Here three values are given one above the other as follows: 86, 0.255, and 330. The top value gives the load in pounds required to compress the spring solid, or the total capacity of the spring. In this case, 86 pounds would be required to compress the spring solid. The second value, 0.255, gives the movement per coil in inches when the spring is compressed from its free height to solid; this value is often known as the "deflection under total load, per coil." In this case then, the deflection, under a load of 86 pounds, is 0.255 inch per coil. The third value, 330, is a constant; if this constant is divided by the number of working coils in the entire spring, the load in pounds required to compress the spring one inch will be found.

Heat-treatment of the Springs — The values given in the tables apply to commercial springs which are "blued" at 600 degrees F., permitted to cool, and then compressed solid, after which they should return to the calculated free height. The values for springs of No. 3 1/2 gage and larger apply to "tempered" springs, the treatment to which they are subjected being as follows: Heat the spring to a red heat and dip it into oil, keeping it in the oil until it is quite cool; then burn off or flash off the oil, which has the same effect as drawing the temper. An exception is made in the case of car springs, which are dipped into oil and taken out again while they still show red or dark red. These springs are not flashed off.

Wire springs of the sizes varying from No. 26 to No. 4 gage, inclusive, are usually allowed to remain in the oil the time required for heating another lot of springs (about seven minutes); the temper is drawn during the last hours of the day when the heat of the furnace is going down, or during the first hour in the morning when the heat of the furnace is coming up. The reason why springs made from the larger sizes of wire require different treatment is that the wire itself has not had the same amount of work put upon it in its manufacture as the smaller sizes, and hence does not have inherent in it the same high tensile strength as the smaller sizes. A fiber stress of 100,000 pounds per square inch is permissible for a spring treated by the hardening processes previously specified, after the spring is coiled.

Relation between Spring Hardness and Movement per Coil. — This process of hardening will also show whether the spring is defective. If a compression spring is compressed solid, the coils, when released, should have a movement per coil as specified in the table. If they do not have this movement, the spring has not been hardened sufficiently. If the space between the coils exceeds that specified in the tables in the line for movement per coil, then the spring is too hard and will not last long. The temper should be drawn until the proper degree of hardness is obtained. The basis of 100,000 pounds per square inch stress, which has been used for calculating the tables, is an ample figure to use for the sizes up to No. 4 gage but may be considered the limiting value for larger sizes.

Using Spring Tables for Stresses other than 100,000 Pounds per Square Inch. — In order to apply the spring tables to stresses other than 100,000 pounds per square inch, it is necessary to take a percentage of the load, as shown in the tables, corresponding to the percentage that the stress required is of 100,000 pounds; thus, if the fiber stress is only 60,000 pounds per square inch, the loads and the movements per coil (or deflections) should be taken at 60 per cent of the values given in the table. For gas engine springs, where the compressions run from 175 to 250 per minute, a fiber stress of 60,000 pounds per square inch is as high as it is safe to assume. In that case, 60 per cent of the figures shown in the table for the load and the movement per coil should be used. The third value given for each size of wire, that is, the constant, remains the same no matter what the fiber stress to which the spring is designed, and is applied in the same manner in all cases.

Example 1: — A spring made from No. 23 spring wire has a mean diameter of ¼ inch and 18 working coils. What weight is required to compress this spring 1 inch? The constant 36, divided by the number of working coils (18), gives a weight of two pounds, which is required to compress the spring 1 inch.

Example 2: — A spring is made from No. 24 wire and has a mean diameter of ¼ inch. How many coils are required to obtain a movement of 1 inch with a load of 1 pound? By dividing the constant 25 by the load (one pound) the number of working coils required is found to equal 25. The constants in all the tables are correct regardless of the fiber stress used, provided the spring has a movement of one inch or more.

Example 3: — A spring is to be designed to work freely over a 1-inch diameter bar; it should have at least a 2-inch total movement, and should compress to a length of 2 inches without the coils touching each other. The spring should be capable of carrying a load of 44 pounds per inch of compression. To work freely over a 1-inch diameter bar, the spring should be made from No. 8½ wire and have a mean diameter of 1¼ inch. Such a spring has a full-load capacity of 120 pounds. The constant is 440, and this constant divided by the load per inch of compression (44) gives the number of working coils required, which is 10. As the diameter of the wire is 5/32 inch, the solid height of the spring with closed ends added will not be more than 1⅞ inch, so that the spring will compress to 2 inches without the coils touching each other, and will fill all requirements.

Example 4: — What load is required to compress a spring 1 inch if it is made from ¼-inch wire having 1 inch mean diameter and 14 working coils? The constant for this spring is 5625. This constant divided by 14 gives 401 pounds required to compress the spring 1 inch.

Example 5: — What would be the free height of the spring specified in the preceding example? The movement per coil or the deflection is 0.109 inch. Add to this the diameter of the wire, 0.250 inch, giving a total space or lead of spring of 0.359 inch. This value multiplied by 14 gives 5.026 inches as the free height of a spring with 14 working coils. Add to this, if the ends are ground, one diameter of wire for the end coils (dead coils) giving a total free height of 5.276 inches. If the ends are not ground, add two diameters of wire.

Navy Specifications for Spring Steel. — Spring steel for the United States Navy Department must be manufactured either by the open-hearth, crucible or electric furnace process. It must contain not less than 0.70, nor more than 1.10 per cent of carbon; not less than 0.25, nor more than 0.50 per cent of manganese; not over 0.25 per cent of silicon; not over 0.04 per cent of phosphorus; and not over 0.04 per cent of sulphur. Vanadium or other elements may be used to obtain the necessary physical requirements, in which case only the phosphorus and sulphur

requirements given need be adhered to. The ultimate tensile strength of the spring steel after heat-treatment must be at least 180,000 pounds per square inch, with an elastic limit of at least 75 per cent of the ultimate tensile strength. It must stand a deflection test as follows: A specimen bar, after having been heat-treated, resting upon supports 24 inches between centers, must not take a permanent set of more than 0.05 inch after the first application of a load corresponding to a fiber stress of 135,000 pounds per square inch, nor a permanent set of more than 7.5 per cent of the total deflection under a load producing a fiber stress of 160,000 pounds per square inch, nor any further set after five additional applications of a load producing a fiber stress of 150,000 pounds per square inch.

These specifications do not apply to drawn round or square wire below 7/16 inch in diameter or size, nor to flats below 3/16 inch in thickness.

Tables for Spring Winding. — The use of the table "Data for Winding Piano Wire Tension Springs" may be best explained by an example. Assume that it is required to wind three different springs: the first to be wound from 0.035-inch wire to fit in an 11/16-inch hole, the second to be wound from 0.040-inch wire to fit in a 3/8-inch hole, and the third to be wound from 0.060-inch wire and to be a sliding fit on a 1/2-inch shaft. The tables show the proper sizes of mandrels for winding to be as follows: For the first spring, 0.562 inch; for the second spring, 0.250 inch; and for the third spring, 0.437 inch. In the latter case, 0.011 inch is allowed for play between spring and shaft. The wire sizes given in the table conform to the English music wire gage.

In all cases when the mandrel diameter is larger than 3/8 inch, the mandrel is mounted in a lathe chuck. Mandrels less than 3/8 inch in diameter are mounted in a drill chuck. In fastening the wire in a lathe chuck, one jaw is usually loosened, and when the mandrel is driven by a drill chuck, the wire is placed between the jaws and the mandrel. If a long spring is required, a mandrel of corresponding length is used, which is ground to an angle of 60 degrees at the end to fit into a female dead center for support. The wire is placed in a bench lathe boring-tool holder or a V-holder in the toolpost. A piece of brass, about 1/8 by 1/2 by 3 inches, is placed between the wire and the toolpost screw. A V-shaped groove is filed in this brass to hold the wire in place. The groove is filed in the lengthwise direction of the brass plate and is made of the proper depth for the size of wire from which the springs are being wound. This clamping arrangement is tightened up with the toolpost wrench, just enough tension being put on the wrench to keep the wire from slipping.

When springs are to be wound, the lathe is geared in the same manner as for screw cutting. The table "Gearing Lathe for Winding Wire Coil Springs" is given to indicate what gearing should be used. The figures in the body of the table give the number of threads per inch for which the lathe should be geared to wind coil springs of a given number of wire gage. The figures in the columns headed "A" are for close-wound tension springs, while the figures in the columns headed "B" are for compression springs. Assume, as an example, that it is required to wind a compression spring of No. 10 Brown & Sharpe gage wire. From the table, it will be seen that this spring should have four and one-half coils per inch, or in other words, that the lathe should be geared the same as for cutting four and one-half threads per inch.

Strength of Brass Wire. — The ultimate tensile strength of brass wire varies widely for different compositions and the strength per square inch increases as the diameter decreases. In general, the ultimate tensile strength of hard-drawn brass wire ranges from about 45,000 to 100,000 pounds per square inch, with higher values for some brass or bronze wires of special composition. Brass wire usually contains from 63 to 67 per cent of copper and from 33 to 37 per cent of zinc. The tensile strength increases with the zinc content within certain limits.

Gearing Lathe for Winding Wire Coil Springs. (See page 483.)

Stresses Produced by Shocks

Stresses in Beams Produced by Shocks. — Any elastic structure subjected to a shock will deflect until the product of the average resistance, developed by the deflection, and the distance through which it has been overcome, has reached a value equal to the energy of the shock. It follows that for a given shock, the average resisting stresses are inversely proportional to the deflection. If the structure were perfectly rigid, the deflection would be 0, and the stress infinite. The effect of a shock is, therefore, to a great extent dependent upon the elastic property (the springiness) of the structure subjected to the impact.

The energy of a body in motion, such as a falling body, may be spent in each of four ways:

1. In deforming the body struck as a whole.
2. In deforming the falling body as a whole.
3. In partial deformation of both bodies on the surface of contact (most of this energy will be transformed into heat).
4. Part of the energy will be taken up by the supports, if these be not perfectly rigid and inelastic.

How much energy is spent in the last three ways it is in most cases difficult to determine, and for this reason it is safest to figure as if the whole amount were spent as in Case 1. In cases where a reliable judgment is possible, as to what percentage of the energy is spent in other ways than the first, a corresponding fraction of the total energy can be assumed as developing stresses in the body subjected to shocks.

From an investigation into the stresses produced by shocks (see MACHINERY, October, 1909), the following conclusions may be drawn: 1. A suddenly applied load will produce the same deflection, and, therefore, the same stress as a static load twice as great. 2. The unit stress p (see formulas in the accompanying table) for a given load producing a shock, varies directly as the square root of the modulus of elasticity E, and inversely as the square root of the length L of the beam and the area of the section. Thus, for instance, if the sectional area of a beam be increased four times, the unit stress will diminish only one-half. This is entirely different from the results produced by static loads where the stress would vary inversely with the area, and within certain limits be practically independent of the modulus of elasticity.

In the table, the expression for the approximate value of p, which is applicable whenever the deflection of the beam is small as compared with the total height h through which the body producing the shock is dropped, is always the same for beams supported at both ends and subjected to shock at *any* point between the supports. In the formulas all dimensions are in inches and weights in pounds.

Stresses Produced in Beams by Shocks

Method of Support, and Point Struck by Falling Body	Fiber (Unit) Stress p produced by Weight Q Dropped Through a Distance h	Approximate Value of p
Supported at both ends; struck in center.	$p = \frac{QaL}{4I}\left(1 + \sqrt{1 + \frac{96\,hEI}{QL^3}}\right)$	$p = a\sqrt{\frac{6\,QhE}{LI}}$
Fixed at one end; struck at the other.	$p = \frac{QaL}{I}\left(1 + \sqrt{1 + \frac{6\,hEI}{QL^3}}\right)$	$p = a\sqrt{\frac{6\,QhE}{LI}}$
Fixed at both ends; struck in center.	$p = \frac{QaL}{8I}\left(1 + \sqrt{1 + \frac{384\,hEI}{QL^3}}\right)$	$p = a\sqrt{\frac{6\,QhE}{LI}}$

I = moment of inertia of section; a = distance of extreme fiber from neutral axis: L = length of beam; E = modulus of elasticity.

Stresses in Helical Springs Produced by Shocks. — A load suddenly applied on a spring will produce the same deflection, and, therefore, also the same unit stress, as a static load twice as great. When the load drops from a height h, the stresses are as given in the accompanying table. The approximate values are applicable

Stresses Produced in Springs by Shocks

Form of Bar from Which Spring is Made	Fiber (Unit) Stress f Produced by Weight Q Dropped a Height h on a Helical Spring	Approximate Value of f
Round	$f = \frac{8\,QD}{\pi d^3}\left(1 + \sqrt{1 + \frac{Ghd^4}{4\,QD^3n}}\right)$	$f = 1.27\sqrt{\frac{QhG}{Dd^2n}}$
Square	$f = \frac{9\,QD}{4\,d^3}\left(1 + \sqrt{1 + \frac{Ghd^4}{0.9\,\pi QD^3n}}\right)$	$f = 1.34\sqrt{\frac{QhG}{Dd^2n}}$

G = modulus of elasticity for torsion; d = diameter or side of bar; D = mean diameter of spring; n = number of coils in spring.

when the deflection is small as compared with the height h. The formulas show that the fiber stress for a given shock will be greater in a spring made from a square bar, than in one made from a round bar, if the diameter of coil be the same, and the side of the square bar equals the diameter of the round bar. It is, therefore, more economical to use round stock for springs which must withstand shocks. This is due to the fact that the deflection for the same fiber stress for a square bar spring is smaller than that for a round bar spring, the ratio being as 4 to 5. The round bar spring is therefore capable of storing more energy than a square bar spring for the same stress.

Shocks from Bodies in Motion. — The formulas given can be applied, in general, to shocks from bodies in motion. A body of the weight W moving horizontally with the velocity of v feet per second, has a stored-up energy:

$$A = \frac{1}{2} \times \frac{Wv^2}{g} \text{ foot-pounds, or } \frac{6\,Wv^2}{g} \text{ inch-pounds.}$$

This expression may be substituted for Qh in the tables in the equations for unit stresses containing this quantity, and the stresses produced by the energy of the moving body thereby determined.

The formulas in the tables give the maximum value of the stresses, providing the designer with something definite to guide him even in cases where he may be justified in assuming that only a part of the energy of the shock is taken up by the member under stress.

TORSIONAL STRENGTH — SHAFTING

General Formula for Torsional Strength. — In the following formulas:

P = load applied at end of lever arm R, in pounds;
R = length of lever arm in inches;
M_t = torsional or twisting moment in inch-pounds;
S = permissible working stress in pounds per square inch;
I_p = polar moment of inertia of cross-section;
y = distance from center of gravity to most remote fiber;
Z_p = section modulus for torsion, or polar section modulus.

Then, for all cross-sections:

$$P \times R = M_t = S \times Z_p.$$

For circular cross-sections:

$$P \times R = M_t = \frac{S \times I_p}{y} = S \times Z_p.$$

(Compare also page 336, "General Formulas for Strength of Materials.")

Polar Moment of Inertia and Polar Section Modulus. — The polar moment of inertia of a surface is the moment of inertia with respect to an axis through the center of gravity, at right angles to the plane of the surface. The polar moment of inertia equals the sum of two moments of inertia taken with respect to two gravity-axes in the plane of the surface at right angles to each other. Thus, for example, the polar moment of inertia of a circle or a square is equal to two times the moment of inertia with respect to an axis in the plane of the surface through the center of gravity.

The polar section modulus or section modulus of torsion for *circular* sections equals the polar moment of inertia divided by the distance from the center of gravity to the most remote fiber. This method of obtaining the polar section modulus may also be applied with fair accuracy to sections that are nearly circular. For other cross-sections, the section modulus of torsion does not equal the polar moment of inertia divided by the distance from the center of gravity to the most remote fiber. The accompanying table gives formulas for the polar section modulus for a number of sections, some of which are not circular. In the latter case, the formulas are approximate.

Polar Moment of Inertia and Polar Section Modulus

Section	Polar Moment of Inertia I_p	Polar Section Modulus Z_p
	$\frac{a^4}{6} = 0.1667\,a^4$	$\frac{2}{9}\,a^3 = 0.22\,a^3 = 0.08\,d^3$
	$\frac{bd\,(b^2 + d^2)}{12}$	$\frac{2}{9}\,bd^2 = 0.22\,bd^2$ (d is the shorter side)
	$\frac{\pi D^4}{32} = 0.098\,D^4$	$\frac{\pi D^3}{16} = 0.196\,D^3$
	$\frac{\pi}{32}\,(D^4 - d^4) = 0.098\,(D^4 - d^4)$	$\frac{\pi}{16}\left(\frac{D^4 - d^4}{D}\right) = 0.196\left(\frac{D^4 - d^4}{D}\right)$
	$\frac{5\sqrt{3}}{8}\,s^4 = 1.0825\,s^4$	$0.92\,s^3 = 0.115\,C^3 = 0.178\,F^3$
	$\frac{\pi D^4}{32} - \frac{s^4}{6} = 0.098\,D^4 - 0.167\,s^4$	$\frac{\pi D^3}{16} - \frac{s^4}{3\,D} = 0.196\,D^3 - 0.333\,\frac{s^4}{D}$
	$\frac{\pi D^4}{32} - \frac{5\sqrt{3}}{8}\,s^4 = 0.098\,D^4 - 1.0825\,s^4$	$\frac{\pi D^3}{16} - \frac{5\sqrt{3}\,s^4}{4\,D} = 0.196\,D^3 - 2.165\,\frac{s^4}{D}$
	$\frac{\sqrt{3}\,s^4}{48} = 0.036\,s^4$	$\frac{s^3}{20} = 0.05\,s^3$

Angle of Torsional Deflection of a Cylindrical Shaft. — Let,

L = length of shaft being twisted, in inches;
D = diameter of shaft, in inches;
T = twisting moment, in inch-pounds;
G = torsional modulus of elasticity, generally assumed as 12,000,000 for steel shafting;
α = angle of torsional deflection in degrees.

Then:

$$\alpha = \frac{583.6\,TL}{D^4G}$$

Example: — Find the torsional deflection for a shaft 4 inches in diameter and 48 inches long, subjected to a twisting moment of 24,000 inch-pounds.

$$\alpha = \frac{583.6 \times 24{,}000 \times 48}{4^4 \times 12{,}000{,}000} = 0.22 \text{ degree, or } 13 \text{ minutes.}$$

Strength of Shafting. — The twisting strength of a shaft is determined from the formula:

$$T = PR = \frac{3.14\,d^3S}{16} = \frac{d^3S}{5.1}$$

or

$$d = \sqrt[3]{\frac{5.1\,PR}{S}} = \sqrt[3]{\frac{321{,}000 \text{ H.P.}}{nS}}$$

in which T = twisting moment in inch-pounds; P = force acting on the shaft, producing rotation, in pounds; R = length of lever arm of force P, in inches; d = diameter of shaft in inches; S = allowable torsional shearing stress in pounds per square inch; n = number of revolutions per minute; and H.P. = horsepower to be transmitted.

The allowable stress for ordinary shafting may be assumed as 4000 pounds per square inch for main power-transmitting shafts; 6000 pounds per square inch for lineshafts carrying pulleys; and 8500 pounds per square inch for small, short shafts, countershafts, etc. The horsepower transmitted using these allowable stresses is as follows:

For main power-transmitting shafts:

$$\text{H.P.} = \frac{d^3n}{80}\text{; or } d = \sqrt[3]{\frac{80 \text{ H.P.}}{n}}$$

For lineshafts carrying pulleys:

$$\text{H.P.} = \frac{d^3n}{53.5}\text{; or } d = \sqrt[3]{\frac{53.5 \text{ H.P.}}{n}}$$

For small, short shafts:

$$\text{H.P.} = \frac{d^3n}{38}\text{; or } d = \sqrt[3]{\frac{38 \text{ H.P.}}{n}}$$

Shafting which is subjected to shocks, sudden starting and stopping, etc., should be given a greater factor of safety than is indicated by the allowable stresses just mentioned.

Example: — What would be the diameter of a lineshaft to transmit 10 horsepower? The shaft makes 150 revolutions per minute.

$$d = \sqrt[3]{\frac{53.5 \times 10}{150}} = 1.53\text{, or, say, } 1\tfrac{9}{16} \text{ inch.}$$

Example: — What horsepower would a short shaft, 2 inches in diameter, carrying but two pulleys close to the bearings transmit? The shaft makes 300 revolutions per minute.

$$\text{H.P.} = \frac{2^3 \times 300}{38} = 63.$$

Torsional Deflection of Shafting. — The shafting must be proportioned not only so that it has the required strength for transmitting a given power, but so that it cannot be twisted through a greater angle than has been found satisfactory by experience. The allowable twist in degrees should, according to some authorities, not be over 5 minutes or about 0.08 degree per foot length of the shaft.

If G = the torsional modulus of elasticity of the material (= 12,000,000); L = the length of the shaft in feet; α = the angle of torsional deflection; and the other letters denote the same quantities as in the formulas just given for the strength of shafting, then the diameter, as determined from the torsional deflection, will be:

$$d = \sqrt[4]{\frac{32 \times 12 \times L \times 360 \times PR}{3.14 \times G \times \alpha \times 2 \times 3.14}}$$

For an angle of deflection equal to 0.08 degree per foot length of the shaft, or a total angle α of 0.08 L,

$$d = 0.29\sqrt[4]{PR} = 4.6\sqrt[4]{\frac{\text{H.P.}}{n}}$$

Example: — Find the diameter of a lineshaft to transmit 10 horsepower at 150 revolutions per minute with a torsional deflection not exceeding 0.08 degree per foot of length.

$$d = 4.6\sqrt[4]{\frac{10}{150}} = 2.35 \text{ inches.}$$

It will be seen, by comparing with the section, "Strength of Shafting," that a larger diameter is required, in this case, to prevent excessive torsional deflection than is required by mere considerations of strength. For short shafts, it is unnecessary to calculate for the angular deflection. It is only in the case of long shafts that this is necessary, and even then only if the torsional deflection would be objectionable.

Linear Deflection of Shafting. — For lineshafting, it is considered good practice to limit the deflection to a maximum of 0.010 inch per foot of length. The maximum distance in feet between bearings, for average conditions, in order to avoid excessive linear deflection, is determined by the formulas:

$$L = \sqrt[3]{720\, d^2} \text{ for bare shafts;}$$

$$L = \sqrt[3]{140\, d^2} \text{ for shafts carrying pulleys, etc.,}$$

in which d = diameter of shaft in inches; L = maximum distance between bearings in feet. Pulleys should be placed as close to the bearings as possible.

Tables of Horsepower Transmitted by Shafting. — The accompanying table, "Horsepower Transmitted by Shafting made from Medium Steel" gives the relation between the diameter of shaft, revolutions per minute, horsepower transmitted, and maximum distance in feet between bearings. Assume, for example, that it is required to find the diameter of a shaft for transmitting 40 horsepower at a speed of 250 revolutions per minute. The shaft is not subjected to any bending action except its own weight. From the table, it is found, by locating "40" in the column under 250 revolutions per minute, that the diameter of the shaft required is 2 inches. The maximum permissible distance between the shaft bearings is slightly more than 14 feet. When the exact horsepower cannot be found in the table, it is advisable to take the nearest larger value listed in the table and find the diameter of shafting required to transmit this horsepower. Tables are also given for the horsepower which can be safely transmitted by cold-rolled and turned steel lineshafting. The table for cold-rolled steel shafting is carried up to 5 inches only, because this diameter is the largest which is cold-rolled at the present time. These tables are used by the transmission department of the Jones & Laughlin Steel Co., and are based on the assumption that bearings are placed at intervals of from 8 to 10 feet and all

pulleys are located as near to the bearings as possible. In these tables, the body part in each gives the number of horsepower to be transmitted. For example, assume that a 3-inch cold-rolled steel lineshaft revolves at a speed of 400 revolutions per minute. Find the power that this shaft can safely transmit. By locating 3 inches in the left-hand column and 400 at the top of the vertical columns, and following the vertical column downward until opposite 3 inches, it is found that under the given conditions 154 horsepower may be safely transmitted.

In general, shafting up to three inches in diameter is almost always made from cold-rolled steel. This shafting is true and straight and needs no turning, but if keyways are cut in the shaft, it must, as a rule, be straightened afterwards, as the cutting of the keyways relieves the tension on the surface of the shaft due to the cold-rolling process. Sizes of shafting from three to five inches in diameter may be either cold-rolled or turned, more frequently the latter, while all larger sizes of shafting must be turned, because cold-rolled shafting is not available in diameters larger than five inches.

Horsepower Transmitted by Turned Steel Lineshafting

Shafting Subjected to Unusual or Severe Stresses. — The formulas given on the preceding pages relate to shafting used under normal conditions. Sometimes the distance between bearings must be abnormally great or the shafts are subjected to very severe stresses between the bearings, due to the gears, pulleys, etc., mounted on it. In such cases, it is necessary to calculate the stresses in the shafting and consider both the weight of the shafting itself and that of the pulleys, gears or other machine parts mounted on it. In calculating the stresses caused by the weight of the shaft itself, the total weight between the bearings is considered as uniformly distributed along the whole shaft, the shaft being considered as a beam freely supported at the bearings. The bending moments caused by pulleys, gears, etc., are then determined and added to find the total bending moment. This, in turn, is then combined with the torsional moment in the manner indicated below.

Combined Bending and Torsional Moments. — One of the most familiar examples of combined stresses in shafting is that of torsion and bending, the torsional stresses being shearing stresses and the bending stresses being tension and compression stresses. As stated under the head "Formulas for Combined Bending and Torsion," where this subject is dealt with in greater detail, the combined moment for ductile materials such as are used for steel shafting, may be written:

$$\text{Combined moment} = \sqrt{M_b^2 + M_t^2} = SZ$$

in which S = the permissible torsional stress in pounds per square inch;

Z = the section modulus for torsion;

M_b = maximum bending moment in inch-pounds;

M_t = torsional moment in inch-pounds.

The accompanying tables "Combined Bending and Torsional Moments" give the combined moment for a number of combinations of bending and torsional moments. For example, a shaft 3½ inches in diameter is subjected to a torsional moment of 36,000 inch-pounds and a bending moment of 35,000 inch-pounds. What is the combined moment and the stresses due to it?

Referring to the tables, and noting that all values may be multiplied by 10, it is found by locating the torsional moment 3600 (instead of 36,000) at the top, and the bending moment 3500 (instead of 35,000) in the left-hand column that the maximum combined moment in this case is 50,210 inch-pounds. Having found the maximum moment, the maximum stress can readily be determined. The section modulus Z for a 3½-inch shaft is 4.2; then the stress $S = 50{,}210 \div 4.2 = 11{,}900$ pounds, approximately.

It should be noted that in the case of shafting, the location and direction of the tooth loads, belt pulls, etc., which produce bending, remain fixed while the shaft rotates. The bending stresses are thus constantly varying in direction, and a greater factor of safety should be used than for a beam subjected to a load in one direction only.

Diameters of Shafts for Combined Torsional and Bending Stresses. — The tables "Diameters of Shafts subjected to Combined Torsional and Bending Stresses" are arranged for fiber stresses of 7500, 10,000 and 12,500 pounds per square inch. As an example, find the diameter of a shaft to sustain a bending moment of 80,000 inch-pounds and a torsional moment of 100,000 inch-pounds, if a fiber-stress of 10,000 pounds per square inch is allowable. By locating the torsional moment, as given in thousands of inch-pounds, at the top of the table, and the bending moment at the left-hand side (in the line and column corresponding to a fiber stress of 10,000 pounds per square inch), the diameter of the shaft corresponding to these moments is found in the body of the table to be 4¾ inches.

Combined Bending and Torsional Moments

All values in the table may be multiplied by 10, 100, 1000, etc., as required, but when any one value is thus multiplied, *all* the other values involved in the same problem must be multiplied by the same factor. The values at the right of the heavy zigzag line across the upper right-hand corner are for bending moments 2000 to 4500, given in the extreme right-hand column.

Table Giving Comparative Torsional Strength and Weight of Hollow and Solid Shafting with Same Outside Diameter

(Upper figures in each line give number of per cent decrease in strength; lower figures give per cent decrease in weight.)

Example: — A 6-inch shaft, with a 4-inch hole through it, has a weight 44.44 per cent less than a solid 6-inch shaft, but its strength is decreased only 19.76 per cent.

Hollow Shafts. — The following is a simple method for finding the dimensions of a hollow shaft which can be substituted for a solid shaft of equal strength to resist bending or torsion.

Let D_1 = diameter of solid shaft;
D = outside diameter of hollow shaft;
d = inside diameter of hollow shaft;
$t = \frac{1}{2}(D - d)$ = thickness of metal of hollow shaft;
$k = d \div D$ = ratio of diameters of hollow shaft.

As the hollow shaft is to have the same strength to resist bending as the solid shaft, the moment of resistance of both must be equal. Hence:

$$\frac{\pi\,(D^4 - d^4)}{32\,D} = \frac{\pi D_1^3}{32}, \text{ from which } D^3 - \frac{d^4}{D} = D_1^3 \qquad (1)$$

If kD is substituted for d in Equation (1):

$$D^3 - D^3k^4 = D_1^3, \text{ from which } \frac{D}{D_1} = \sqrt[3]{\frac{1}{1 - k^4}} \qquad (2)$$

In a similar manner, by substituting $\frac{d}{k}$ for D in Equation (1):

$$\frac{d}{D_1} = k\sqrt[3]{\frac{1}{1-k^4}} \tag{3}$$

Further, as $t = \frac{1}{2}(D - d)$, Formula (4) is found by substitution and simplification:

$$\frac{t}{D_1} = \frac{1-k}{2}\sqrt[3]{\frac{1}{1-k^4}} \tag{4}$$

In the accompanying table the values of the factors containing k in Equations (2), (3), and (4) are calculated for certain values of k. The bottom line of the table gives the weight of the hollow shaft in per cent of that of the solid.

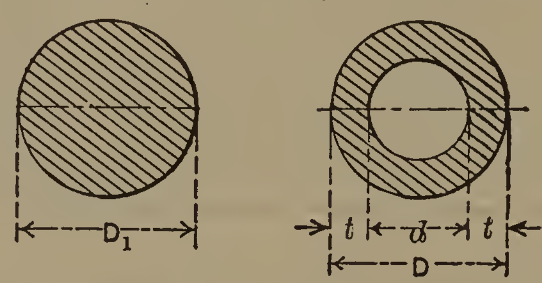
It is evident that Equation (1) would be the same, if it were derived under the assumption that the hollow shaft had the same torsional strength as the solid one, instead of having the same strength against bending, as assumed. The table will therefore hold true for shafts subjected to bending or torsion, or both.

Assume, as an example, that a solid shaft 3 inches in diameter is to be replaced by a hollow shaft, ratio k being 0.5. Then, by inserting the value found from the table in Equation (2):

$$\frac{D}{D_1} = 1.021 \text{ and } D = 3 \times 1.021 = 3.063 \text{ inches,}$$

$$d = 0.5\,D = 1.532 \text{ inch.}$$

Table of Factors for Finding Dimensions of Hollow Shafts to Replace Solid Shafts



Ratio of	Ratio $d \div D$

$d \div D_1 =$	0.510	0.567	0.628	0.694	0.767	0.851	0.951	1.087	1.284
$t \div D_1 =$	0.257	0.232	0.209	0.186	0.164	0.141	0.119	0.096	0.071
Weight of hollow shaft*...	78.3	74.35	70.2	65.8	61.3	56.4	51.6	45.4	38.7

* Weight of hollow shaft is given in per cent of weight of solid shaft.

The use of hollow shafts not only reduces the weight of a shaft for a given strength, but increases the reliability of the shafting, on account of the removal of the metal from the core of the shaft. This applies especially to shafts of large diameters, as in large steel ingots the central core is likely to be less dense than the outer portion and to show shrinkage cavities near the center. If the ingot is bored out, the spongy or "piped" portion will be removed, and the metal remaining will be superior in quality to that in a solid shaft. Ingots for shafting should, however, not be cast hollow, but be bored out after having been cast solid.

FRICTION

Friction is the resistance to motion which takes place when one body is moved upon another, and is generally defined as "that force which acts between two bodies at their surface of contact, so as to resist their sliding on each other." The force of friction, F, bears — according to the conditions under which sliding occurs — a certain relation to the pressure between the two bodies; this pressure is called the normal pressure N. The relation between force of friction and normal pressure is given by the *coefficient of friction*, generally denoted by the Greek letter μ. Thus:

$$F = \mu \times N, \quad \text{and} \quad \mu = \frac{F}{N}$$

Example: — A body weighing 28 pounds rests on a horizontal surface. The force required to keep it in motion along the surface is 7 pounds. Find the coefficient of friction.

$$\mu = \frac{F}{N} = \frac{7}{28} = 0.25$$

If a body is placed on an inclined plane, the friction between the body and the plane will prevent it from sliding down the inclined surface, provided the angle of the plane with the horizontal is not too great. There will be a certain angle, however, at which the body will just barely be able to remain stationary, the frictional resistance being very nearly overcome by the tendency of the body to slide down. This angle is termed the angle of repose, and the tangent of this angle equals the coefficient of friction. The angle of repose is frequently denoted by the Greek letter θ. Thus, $\mu = \tan \theta$.

A greater force is required to start a body from a state of rest than to merely keep it in motion, because the *friction of rest* is greater than the *friction of motion*.

Rolling Friction. — When a body rolls on a surface, the force resisting the motion is termed *rolling friction*. This has a different value from that of the ordinary, or sliding, friction. Let W = total weight of rolling body or load on wheel, in pounds; r = radius of wheel, in feet; f = coefficient of rolling friction. Then:

$$\text{Resistance to rolling, in pounds} = \frac{W \times f}{r}$$

The coefficient of rolling friction varies with the conditions. For wood on wood it may be assumed as 0.005; for iron on iron, from 0.002 to 0.005; iron on granite, 0.007; iron on asphalt, 0.012; iron on wood, 0.018.

Laws of Friction. — The earliest experiments made on friction, which led to the establishment of definite laws, were undertaken by Morin and Rennie about 1830. The laws laid down by these early investigators, however, have been considerably modified by later investigations. The following may be considered as a correct statement of the laws of friction in their modified form, for unlubricated or dry surfaces.

1. For low pressures the friction is directly proportional to the normal pressure between the two surfaces. As the pressure increases to a high value the friction does not rise as rapidly; but when the pressure becomes abnormally high, the friction increases at a rapid rate until seizing takes place.

2. The friction both in its total amount and its coefficient is independent of the areas in contact, so long as the total pressure remains the same. This is true for moderate pressures only. For high pressures, this law is modified in the same way as in the first case.

3. At very low velocities the friction is independent of the velocity of rubbing. As the velocities increase, the friction decreases.

Lubricated Surfaces. — For well lubricated surfaces, the laws of friction are considerably different from those governing dry or poorly lubricated surfaces.

1. The frictional resistance is almost independent of the pressure per square inch, if the surfaces are flooded with oil.

2. The friction varies directly as the speed, at low pressures; but for high pressures the friction is very great at low velocities, approaching a minimum at about two feet per second linear velocity, and afterwards increasing approximately as the square root of the speed.

3. For well lubricated surfaces the frictional resistance depends, to a very great extent, on the temperature, partly because of the change in the viscosity of the oil and partly because the diameter of the bearing increases with the rise of temperature more rapidly than the diameter of the shaft, thus relieving the bearing of side pressure.

4. If the bearing surfaces are flooded with oil, the friction is almost independent of the nature of the material of the surfaces in contact. As the lubrication becomes less ample, the coefficient of friction becomes more dependent upon the material of the surfaces.

Experiments made by Tower indicate that the oil bath is very much superior to any other method of lubrication. Under conditions when with an oil bath the coefficient of friction was 0.0014, the value of this coefficient with a syphon lubricator was 0.0098, and with a pad under the journal, 0.009. This indicates that the friction when using an oil bath is only about one-seventh of the friction when using other methods of lubrication.

The comparative value of different lubricants is indicated by the same experiments. If the friction of a journal in its bearing, using a sperm oil bath, is assumed equal to 1, the friction using rape oil is 1.06; mineral oil, 1.29; lard oil, 1.35; olive oil, 1.35; and mineral grease, 2.17.

Lubricants. — The value of an oil as a lubricant depends mainly upon its film-forming capacity; that is, its capability of maintaining a film of oil between the bearing surfaces. The film-forming capacity depends to a large extent on the viscosity of the oil, but this should not be understood to mean that the oil of the highest viscosity is in every case the most suitable lubricant. On the other hand, an oil of the lowest viscosity which will retain an unbroken oil film between the bearing surfaces is the most suitable for purposes of lubrication, because a higher viscosity than that necessary to retain the oil film results in a waste of power, due to the expenditure of energy necessary to overcome the internal friction of the oil itself. For internal lubrication, only mineral oil of good quality should be used. Vegetable or animal oils are unsuitable owing to the fact that they decompose at high temperatures, forming acids which are injurious to metals. (See section on "Bearing Lubricants," page 533.) It is of importance to note that the following oils have a tendency to corrode the metals mentioned: Tallow oil, iron and copper; seal oil, copper; whale oil, lead; lard oil, lead; sperm oil, lead and zinc; rape oil, copper; cottonseed oil, tin.

Tables of Coefficients of Friction. — As the coefficient of friction depends on so many variable factors, it is impossible to give data that can be depended upon to meet all conditions, except in a very general way. The accompanying tables, however, give coefficients of friction as determined by various experimenters with different materials, conditions of loading and kinds of lubricants. The surfaces in contact, especially when poorly lubricated or dry, largely influence the coefficient of friction, which, of course, diminishes with the increasing smoothness of the surface.

Experiments by Thurston, to determine the coefficients of friction of motion and of rest of a journal, show that with a rubbing speed of 2.5 feet per second, using sperm oil as a lubricant, the coefficients at the starting were about five times the coefficients of motion, for a pressure of 50 pounds per square inch. As the pressure was increased to 500 pounds per square inch, the coefficient at starting was about thirty times greater than that of motion. With lard oil, the ratio between the two coefficients at 50 pounds pressure per square inch was about 3.5, and at 500 pounds pressure per square inch, about 20.

Coefficients of Friction

Low pressures (14 to 20 pounds per square inch). Sliding friction.

Influence of Friction on the Efficiency of Small Machine Elements. — The friction between machine parts lowers the efficiency, or the ratio of the power possible to take out of a machine element and that put into it. In the following are given average values of the efficiency, in per cent, of the most common machine elements when carefully made. Ordinary bearings, 95 to 98; roller bearings, 98; ball bearings, 99; spur gears with cast teeth, including bearings, 93; spur gears with cut teeth, including bearings, 96; bevel gears with cast teeth, including bearings, 92; bevel gears with cut teeth, including bearings, 95; belting, from 96 to 98; high-class silent power transmission chain, 97 to 99; roller chains, 95 to 97.

Friction of Journals. — The general laws of friction, as applied to unlubricated surfaces, do not hold true when a bearing is properly lubricated. From experiments by Thurston and Tower, the friction of a journal per square inch of bearing surface for any given speed and velocity of rubbing is equal to:

$$F = kp^n v^m$$

in which F = force of friction at the rubbing surface, in pounds per square inch;
k = a constant which varies with the quality of the lubricant, being 0.02 for the best and 0.04 for the lower grades;
p = normal pressure in pounds per square inch of bearing surface;
n = exponent depending upon the manner of oiling; its value is 1, in the case of dry surfaces; 0.50, in the case of drop-feed lubrication; 0.40, in the case of ring and pad lubrication; and 0, in case oil is forced into the bearing under sufficient pressure to float the shaft.
v = the velocity of rubbing, in feet per second;
m = exponent varying from 0, in the case of dry surfaces, to 0.20, in the case of drop-feed, and 0.50, in the case of an oil bath.

From this formula, it will be seen that the friction increases with the load on the bearing and also with the velocity of rubbing, but at a much slower rate than either.

Coefficients of Journal Friction

Cast iron journal in bronze bearing. Velocity of rubbing surface, 12 feet per second. Intermittent oil feed through an oil-hole.

* Pressure 573 pounds per square inch.

BEARINGS

Generation of Heat in Bearings. — The rise in temperature of a bearing above that of the surrounding air, due to the friction of the surfaces, varies from less than 10 to nearly 100 degrees F., and is commonly about 30 degrees F. In order to limit the amount of heat in the bearing, it is necessary to limit the work of friction to a certain definite value per square inch of bearing area. As the work of friction is due to the bearing pressure per square inch and the velocity of rubbing, the product of these two quantities should not exceed a certain value.

The limiting value for the product of pressure and velocity is determined by Thurston's formula:

$$pv = C$$

in which p = bearing pressure, in pounds per square inch;
v = velocity of rubbing, in feet per second;
C = constant having values varying from 800 foot-pounds per second, in the case of iron or low-carbon steel shafts, to 2600 foot-pounds, in the case of high-carbon steel crankpins.

This formula is satisfactory for bearings running at ordinary speeds, although it must be modified for extreme cases.

Influence of Quality of Oil. — The thicker and less free-flowing an oil is, the greater the unit pressure it will stand in a bearing without squeezing out. A watch oil or a light spindle oil can only be used under a very small unit pressure. Sometimes they are squeezed out of the bearing when the pressure does not exceed 50 pounds per square inch. A cylinder oil of good body will stand a pressure of over 2000 pounds per square inch in the same bearing. It is important to determine, if possible, in each case, what quality of oil is best adapted to each particular bearing.

The allowance commonly made for the running fit of the box and shaft is about $0.0005\ (D + 1)$, in which D is the nominal diameter of the shaft in inches. Some manufacturers of fast-running machinery make the diameter of the box exceed that of the shaft by nearly twice this amount. The oil should be introduced at that point where the forces acting tend to separate the shaft and the box. At this point, grooves must be cut in the surface of the box so as to distribute the lubricant evenly over the entire length of the journal. Additional oil grooves should not be used, as these merely tend to rupture the oil film. Their only purpose is to distribute the supply of lubricant over the whole length of the journal surface and to collect the oil which would otherwise run out at the ends of the bearing and return it to some point where it may again be used.

Calculating Dimensions of Bearings. —The first consideration is the allowable pressure p in pounds per square inch of projected area of bearing. The amount of pressure that commercial oils will endure at low speeds without rupture of the oil film varies from 500 to 1000 pounds per square inch, when the load is steady. It is not safe, however, to load a bearing to this extent, since it is only under favorable circumstances that the film will stand this pressure. On this account, journal bearings should not be required to stand more than two-thirds of this pressure at slow speeds and the pressure should be reduced when the speed increases, except in cases of very perfect lubrication. The approximate unit pressure which a bearing will endure without seizing is:

$$p = \frac{PK}{DN + K} \qquad (1)$$

in which p = allowable pressure in pounds per square inch of projected area;
D = diameter of bearing in inches;

N = number of revolutions of journal per minute;

P = maximum safe unit pressure under given circumstances at slow speed. Ordinarily the value of P is 200 for collar thrust bearings; 400 for shaft bearings; 800 for car journals; 1200 for crankpins; and 1600 for wrist-pins. Under exceptional circumstances, these values may be increased by as much as 50 per cent, but only when the workmanship is the best and the care of the bearing the most skillful; in addition, a bearing should be readily accessible and the oil of the best quality and unusually viscous. Only in the case of very large machinery, which will have the most expert supervision, can these higher values be safely adopted.

K = quantity depending on method of oiling, etc. Its value may be assumed for ordinary work, drop-feed lubrication, as 700; first-class care, drop-feed lubrication, 1000; for force-feed lubrication or ring oiling, 1200 to 1500; extreme limit for perfect lubrication and air-cooled bearings, 2000. The value of 2000 is seldom used except in locomotive work where the rapid circulation of the air cools the journals. Higher values than 2000 may be used only in the case of water-cooled bearings.

Formula (1) is in a convenient form for calculating journals. In case the bearing is some form of sliding shoe, the quantity 240 V should be substituted for the quantity DN in the equation, V being the velocity of rubbing in feet per second.

There are a few cases where a unit pressure sufficient to break down the oil film is allowable. Such cases are the pins of punching and shearing machines, pivots of swing bridges and similar constructions, where the motion is slow and heating cannot well result. In such cases, pressures up to 4000 pounds per square inch are permissible.

Diameter of Shaft or Pin. — The diameter of a shaft or pin must be such that it will be strong and stiff enough to carry the load. In order to design it for strength and stiffness, the approximate length must be known. This will be assumed from the following equation:

$$L = \frac{20\,W\sqrt{N}}{PK} \tag{2}$$

in which L = length of bearing in inches;
W = total load upon bearing in pounds;
N = number of revolutions of journal per minute;
P and K = same quantities as in Equation (1).

When the approximate length has been found by the use of this equation, the diameter of the shaft or pin may be found by the general formulas for the strength of materials. The length of the journal must then be recomputed by the formula given in the next paragraph.

Length of Bearing. — Having obtained the proper diameter, a bearing length must be selected long enough so that the unit pressure shall not exceed the required value. This length may be found directly from the equation:

$$L = \frac{W}{PK}\left(N + \frac{K}{D}\right) \tag{3}$$

in which L = length of bearing in inches;
W = total load upon bearing in pounds;
P, K, N and D = same quantities as in Equation (1).

Should the length obtained by this formula not give practical dimensions for proper proportions, the diameter and length of the bearing must be adjusted to meet the conditions. A good rule for the length of the journal, after the requirements with relation to the bearing pressures have been met, is to make the ratio of the length to the diameter about equal to 1/8 of the square root of the number of revolutions per minute. This quantity may be decreased from 10 to 20 per cent in the case of crankpins and increased in the same proportion in the case of shaft bearings, but should not be departed from too widely. In the case of an engine making 100 revolutions per minute, the length of the bearings would, by this rule, be from 1¼ to 1½ times the diameter. In the case of a motor running at 1000 R.P.M., the bearings would be about 4 diameters long. This rule, while it cannot be adhered to on all occasions, is an excellent guide.

Example: — Design a collar thrust bearing for a 10-inch propeller shaft running at 150 revolutions per minute, and with a thrust of 60,000 pounds. Assuming that the thrust rings will be 2 inches wide, their mean diameter will be 12 inches. From Equation (1) we will have for the allowable bearing pressure $\frac{200 \times 700}{12 \times 150 + 700}$, or 56 pounds per square inch. This will require a bearing of 60,000 ÷ 56, or 1070 square inches area. Since each ring has an area of 0.7854 ($14^2 - 10^2$), or about 75 square inches, the number of rings needed will be 1070 ÷ 75, or 14. In case it were desirable to keep down the size of this bearing, the constant K might have been given values as high as 1000 instead of 700.

Example: — Design a main bearing for a horizontal engine. Assume that the diameter of the shaft is 15 inches and that the weight of the shaft, flywheel, crankpin, one-half of the connecting-rod, and any other moving parts that may be supported by the bearings, is 120,000 pounds, and that two-thirds of this weight comes on the main bearing, the remainder coming on the outboard bearing. The engine runs at 100 revolutions per minute. In this case, $W = 80{,}000$ pounds, $P = 400$ pounds per square inch, and K depends upon the care and method of lubrication. Assuming that the bearing will be flushed with oil by some gravity system, and that, since the engine is large, the care will be excellent, take $K = 1500$. This gives the length of the bearing from Formula (3):

$$L = \frac{80{,}000}{400 \times 1500}\left(100 + \frac{1500}{15}\right) = 26\tfrac{1}{2} \text{ inches (about).}$$

In computing the length of this bearing, the pressure of the steam is not considered since it is not a steady pressure; but the projected area of the main bearing must be greater than the projected area of the crankpin.

Example: — Find the dimensions for the bearings of a 100,000-pound hopper car weighing 40,000 pounds, having eight 33-inch wheels. The journals are 5½ inches in diameter, and the car is to run at 30 miles per hour. The wheels will make 307 revolutions per minute when running at this speed, and the load on each journal will be 140,000 ÷ 8, or 17,500 pounds. Although the journal will be well lubricated by means of an oil pad, it will receive but indifferent care, so the value of K will be taken as 1200. The length of the journal will then be:

$$L = \frac{17{,}500}{800 \times 1200}\left(307 + \frac{1200}{5.5}\right) = 9\tfrac{5}{8} \text{ inches (about).}$$

Example: — Design a crankpin for an engine with a 20-inch steam cylinder running at 80 revolutions per minute, and having a maximum unbalanced steam pressure of 100 pounds per square inch. The maximum and not the mean steam pressure should be taken in the case of crank- and wrist-pins. The total steam load on the piston is 31,400 pounds. P will be taken as 1200, and K as 1000. By Formula (2):

$$L = \frac{20 \times 31,400 \times \sqrt{80}}{1200 \times 1000} = 4.7, \text{ or, say, } 4\tfrac{3}{4} \text{ inches.}$$

In order that the deflection of the pin shall not be sufficient to destroy the lubricating film:

$$D = 0.09 \sqrt[4]{WL^3}$$

which limits the deflection to 0.003 inch. Substituting in this equation, the diameter becomes 3.85, or, say, $3\frac{7}{8}$ inches. With this diameter, obtain the length of the bearing, by using Formula (3):

$$L = \frac{31,400}{1200 \times 1000}\left(80 + \frac{1000}{3\frac{7}{8}}\right) = 8.85, \text{ say, } 9 \text{ inches.}$$

The mean of this value and the one obtained before is about 7 inches. Substituting this in the equation for the diameter, $D = 5\frac{1}{4}$ inches. Substituting this new diameter in Equation (3):

$$L = \frac{31,400}{1200 \times 1000}\left(80 + \frac{1000}{5\frac{1}{4}}\right) = 7.1, \text{ say, } 7 \text{ inches.}$$

It would now be preferable to take about half an inch off the length of this pin, and add it to the diameter, making it $5\frac{3}{4} \times 6\frac{1}{2}$ inches, and this will be found to bring the ratio of the length to the diameter nearer to one-eighth of the square root of the number of revolutions.

Bearing Pressures for Various Classes of Bearings (Kimball and Barr)

Class of Bearing and Condition of Operation		Allowable Bearing Pressure, Lbs. per Sq. In.
Bearings for very slow speed as in turntables in bridge work		7000 to 9000
Bearings for slow speed and intermittent load as in punch presses		3000 to 4000
Locomotive Wrist-pins		3000 to 4000
Locomotive Crankpins		1500 to 1700
Locomotive Driving Journals		190 to 220
Railway Car Axles		300 to 325
Marine Engine Main Bearings	naval practice	275 to 400
	merchant practice	400 to 500
Marine Engine Crankpins		400 to 500
Stationary Engine Main Bearings (high speed)	for dead load*	60 to 120
	for steam load	150 to 250
Stationary Engine Crankpins (high speed)	overhung crank	900 to 1500
	center crank	400 to 600
Stationary Engine Wrist-pins (high speed)		1000 to 1800
Stationary Engine Main Bearings (slow speed)	for dead load*	80 to 140
	for steam load	200 to 400
Stationary Engine Crankpins (slow speed)		800 to 1300
Stationary Engine Wrist-pins (slow speed)		1000 to 1500
Gas Engines, Main Bearings		500 to 700
Gas Engines, Crankpins		1500 to 1800
Gas Engines, Wrist-pins		1500 to 2000
Heavy Lineshaft Brass or Babbitt Lining		100 to 150
Light Lineshaft Cast-iron Bearing Surfaces		15 to 25
Generator and Dynamo Bearings		30 to 80

* Weight of shaft, flywheels, etc.

Relation of Length l to Diameter d of Journals

Type of Bearing	Values of $\frac{l}{d}$
Marine Engine Main Bearings	1 to 1.5
Marine Engine Crankpins	1 to 1.5
Stationary Engine Main Journals	1½ to 2.5
Stationary Engine Crankpins	1
Stationary Engine Crosshead Pins	1 to 1.5

High-speed Bearings. — In carefully lubricated high-speed bearings, very high unit pressures are permissible. The following figures represent the practice of a large concern building electrical machinery in large units:

Velocity in feet per second of rubbing surfaces	20	30	40	60	75
Permissible pressure in pounds per square inch	165	190	205	225	230

It will be seen that the permissible pressures increase with the speed. The reason for this is that the higher the surface speed, the more effectively is the lubricant dragged in against the hydraulic pressure due to the load carried, the high-speed bearing acting in a measure as a pump for its lubricant.

Allowance for Oil between Shaft and Journal in Medium and High-speed Bearings

Diameter of Journal	Allowance	Diameter of Journal	Allowance	Diameter of Journal	Allowance
⅜ to 1	0.002	6	0.009	12	0.016
1⅛ to 2½	0.003	7	0.011	13	0.017
2⅝ to 3½	0.004	8	0.012	14	0.018
3⅝ to 4½	0.005	9	0.013	15	0.019
5	0.006	10	0.014	16 to 24	0.020
5½	0.007	11	0.015	....	....

Thrust Bearings. — Flat thrust bearings should be made of an annular form having an inside diameter one-half of the external diameter. Experiments carried out by Schiele to determine the wear in pivot bearings show that the wear is theoretically along a line called the *tractrix*, and that an end-thrust bearing made of this form will have the wear in the direction of the axis of a thrust shaft uniform at all points, but it has been shown in practice that little is to be gained by the use of bearings having this complicated shape. Experiments made on flat pivot thrust bearings, three inches in diameter, indicate that the coefficient of friction between a steel pivot and a manganese-bronze bearing, properly lubricated, using two radial oil-grooves only, varies from 0.018 at 50 revolutions per minute, to an average of 0.011 at 350 revolutions per minute. If four radial oil-grooves are used instead of two, the friction is approximately doubled, due to rupture of the oil film.

The load that may be safely carried by a thrust bearing varies with the velocity of the rubbing surfaces. The table following may be used as a guide in designing bearings in which the shaft is made from wrought iron or steel and the bearing from bronze or brass, and which have ample lubrication. In general, it is possible to use bath lubrication for thrust bearings, that is, the running surfaces are submerged constantly in a bath of oil. If the shaft is made from cast iron running on bronze or brass bearings, the values in the table for allowable pressure should be only one-half of those given.

Allowable Pressure, in Pounds per Square Inch, on Thrust Bearings

Average Velocity of Rubbing Surface, Feet per Minute	Safe Pressure, Lbs. per Sq. In.	Average Velocity of Rubbing Surface, Feet per Minute	Safe Pressure, Lbs. per Sq. In.
Slow and intermittent	1500	100 to 150	75
50	200	150 to 200	60
50 to 100	100	Over 200	50

Collar Thrust Bearings. — In collar thrust bearings, the thrust is taken by projections or shoulders on the shaft, often at some distance from its end. This type of bearing is used when a greater thrust than can be conveniently placed on a single flat or step bearing is to be taken care of. In a well-made bearing, each of the collar surfaces takes its proportionate part of the load, and it is thus possible, without using excessive diameters, to properly distribute a very great thrust on a number of collars formed solidly with the shaft, by cutting a number of grooves in the latter. One advantage of the collar bearing is that the difference between the outer and inner diameters of the bearing surface is not very great, and hence the velocities at the outer and inner edges do not vary appreciably; this, again, eliminates unequal wear on the thrust collar surfaces. The safe load that may be placed on collar thrust bearings varies between 60 to 100 pounds per square inch.

Bi = bismuth; P = phosphorus; Fe = iron; Na = sodium.

Hydraulically Supported Step Bearings. — The type of thrust bearing which is hydraulically supported has very little frictional resistance and is adapted to heavy pressures and high speeds. Bearings of this type which have been applied to Curtis vertical steam turbines are so designed that oil (water may also be used with this type of bearing), under sufficient pressure to sustain the load, is forced between recessed plates at the bottom of the shaft and then passes out radially in the form of a thin film and up through a cylindrical guide bearing located just above the bottom plates, thus floating the shaft upon the oil film.

Thrust Bearing Design Based on Principle of Wedge-shaped Oil Film. — The investigations of Professor Osborne Reynolds, following the experiments of Tower on well fitted car journals and brasses flooded with oil, showed that the oil, because of its viscosity and adhesion to the journal, is, by the journal rotation, dragged into a wedge-shaped space between the journal and brass. This action sets up pressure in the oil film which, in turn, supports the load, thus separating the bearing surfaces. The design of the Kingsbury thrust bearing is based on this principle, the bearing floating the load on wedge-shaped oil films which form automatically and without employing a high pressure oil pump. There is usually a flat, annular, revolving plate with the bearing face immersed in oil and supported on one or more shoes which are mounted to tilt as required by running conditions. These bearings are made for both horizontal and vertical shafts. The low-speed bearings may be loaded to 1000 pounds or more per square inch when using heavy oil, and high-speed bearings with light oils regularly carry loads up to 500 pounds per square inch. The friction loss in this bearing is very low. According to an approximate rule for vertical bearings having six shoes with the inside diameter one-half the outside diameter and loaded to 350 pounds per square inch of shoe area, the mean coefficient of friction is 0.00009 times the square root of the revolutions per minute and varies inversely as the square root of the unit pressure, when using dynamo oil having a temperature of about 40 degrees C. The coefficient of friction has been found by a large number of tests to vary between 0.0008 and 0.003.

Frictional Power Losses in Bearings. — In the following formulas for determining power losses due to friction, W = work expended in friction in foot-pounds per minute; μ = coefficient of friction; L = total load in pounds on bearing; D = diameter (cylindrical bearing); R = maximum radius (step or thrust bearing); r = minimum radius; N = revolutions per minute; α = one-half included angle (conical pivot bearing); M = moment of friction in inch-pounds. Then, $W = \frac{2\pi MN}{12}$. The values of M and W for different bearings are as follows: *Shafts and journals:* $M = \frac{1}{2}\mu LD$ and $W = \frac{2\pi\mu LDN}{24} = 0.2618\,\mu LDN$. *Flat pivot or step bearing:* $M = \frac{2}{3}\mu LR$ and $W = 0.349\,\mu LRN$. *Collar thrust bearing:* $M = \frac{2}{3}\mu L\frac{R^3 - r^3}{R^2 - r^2}$ and $W = 0.349\,\mu LN\frac{R^3 - r^3}{R^2 - r^2}$. *Conical pivot bearing:* $M = \frac{2}{3}\mu LR$ cosec α and $W = 0.349\,\mu LRN$ cosec α. *Truncated conical pivot:* $M = \frac{2}{3}\mu L\frac{R^3 - r^3}{R\sin\alpha}$ and $W = 0.349\,\mu LN\frac{R^3 - r^3}{R\sin\alpha}$. *Hemispherical step bearing and Schiele's tractrix pivot:* $M = \mu LR$ and $W = 0.5236\,\mu LRN$. For flat bearing surfaces in general $W = \mu LS$ in which S = rate, in feet per minute, at which sliding action occurs.

Knife-edge Bearings. — The knife-edge bearings of weighing and testing apparatus should be made of steel having 0.90 to 1.00 per cent carbon. An angle of 90 degrees is recommended for knife-edge bearings. The seats for supporting the pivots should be drawn to a light straw color and the pivots slightly darker. The bearing edge may be left sharp for loads up to 1000 pounds per inch of length; for heavier loads the edge is dulled slightly with an oilstone.

Bearing Metals. — Bearing metals are usually composed of alloys of copper, lead, tin, antimony and zinc, and are known as babbitt metal, white metal, brass, phosphor-bronze, and by various trade names. The price of these bearing metals depends largely upon the constituents. Lead and zinc are cheapest, with antimony, copper, and tin increasing progressively in price in the order named, tin being the most expensive. The more lead is used in a bearing, the cheaper it will be. Lead, however, is too soft to be used alone and must be alloyed with one of the other metals. Antimony added to lead increases the hardness and brittleness; with tin added, a tougher alloy is obtained. Nearly all the various babbitt metals are alloys of lead, tin and antimony. In such babbitts, the wear generally increases with an increase of antimony and the price with an increase of tin. High antimony babbitts are used in heavy machinery because they are harder, while those low in antimony are used in high-speed machinery. Soft babbitts do not have sufficient strength to sustain the weight and shocks incident to heavy machinery bearings.

The table "Composition of Bearing Metals" gives the constituents of some of the metals on the market. Wide deviation in the composition of babbitt is shown in the table. The first babbitt in the table is a fairly good alloy for high-speed machinery, but is not very hard. Its melting point is about 500 degrees F. The second babbitt is somewhat harder and melts at a higher temperature. Both of these are largely used for lining purposes. The fourth babbitt is widely used for heavy machinery and the sixth has good wearing properties, but cannot be used for high speeds. The white metals are used extensively for bearings in generators, motors, electric cars, etc. Alloys containing sodium have the peculiar property of producing, by oxidation, material which will saponify with the oil used in the bearing and thus assist lubrication. The alloys of lead, copper and tin usually are provided with a thin lining of lead or of a soft babbitt; this combination wears better than an entire bearing of the soft metal. The "P. R. R. car brass, B" is considered one of the best bearing bronzes that can be obtained. It contains approximately the smallest quantity of tin that will hold the lead alloyed with the copper. The table "Composition of Bronzes" gives a list of alloys used by the U. S. Navy Department.

Composition of Bronzes

	Parts
White Metal:	
Tin	7.6
Copper	2.3
Zinc	83.3
Antimony	3.8
Lead	3.0
Hard Bronze for Piston Rings:	
Tin	22.0
Copper	78.0
Brazing Metal:	
Copper	85.0
Zinc	15.0

Tin	1
Zinc	¼
Anti-friction Metal:	
Copper — (best refined)	3.7
Banca tin	88.8
Regulus of antimony	7.5

Well fluxed with borax and rosin in mixing.

The exact composition of the original babbitt metal is not known. The ingredients were copper, tin and antimony in approximately the following proportions: 89.3 per cent tin; 3.6 per cent copper; 7.1 per cent antimony. This metal possesses great anti-frictional qualities, but the high percentage of tin makes it expensive and has led to the substitution of other metals which are marketed under the name of babbitt metal. These cheaper grades, when properly made, are for some purposes superior to the original babbitt metal. The composition of metals for different classes of bearings frequently used is given in the following table:

Babbitt Metal Compositions

Class of Service Adapted for	Composition of Metal			
	Tin	Antimony	Copper	Lead
High-pressure bearings	90	7	3	....
High pressure and fast speed	86	12	2	....
Medium pressure and high speed	30	20	....	50
Medium pressure and medium speed	15	25	....	60
Low pressure and medium speed	8	20	....	72
Principally for shaftings, etc.	....	10	....	90

American Society for Testing Materials Specifications for Babbitt Metals.— A sub-committee of the American Society for Testing Materials has proposed to reduce the large number of babbitt metals in use to five, a number which the committee think will be ample for every class of work. The following table gives the composition of the series which it is believed covers the range for all requirements:

Number	Tin, Per cent	Antimony, Per cent	Copper, Per cent	Lead, Per cent
1	83.33	8.33	8.33	....
2	89.00	7.00	4.00	....
3	50.00	15.00	2.00	33.00
4	5.00	15.00	....	80.00
5	....	10.00	....	90.00

High-grade Bearing Metal. — A high-class bearing metal is prepared as follows: Melt 7 parts of copper at as low a heat as possible; then add 25 parts of antimony and 200 parts of tin. This mixture is cast in iron ingot molds. It is then re-melted and to each five pounds of the ingots is added eight pounds of tin, this second alloy being cast in bars to suit the requirements.

Babbitting. — Babbitt metal is extensively used as a lining for bearings, not only for its anti-frictional qualities, but because it is much cheaper than a machined box. It is easily melted, and by the use of a babbitting mandrel, the diameter of which is equal to, or slightly greater than, the journal, the operation of machining the bearing can often be eliminated. In bearings which are comparatively large and important, the mandrel is sometimes made smaller than the finished bearing and the latter is bored after the metal has been expanded and compressed. The lining of a two-part bearing is commonly expanded by the peen of a hammer, whereas, for small solid bearings, the same practical result is obtained by forcing through a tapered arbor in a broaching press or by other means, the size of the arbor being such as to leave sufficient metal for reaming or boring.

Prior to pouring the babbitt, the bearing should be heated to prevent the molten metal from becoming chilled and sluggish. Bronze shells which are to have babbitt linings should first be tinned by immersing in a pot of molten solder. Use solder of "half and half" composition, and zinc chloride as a flux. The shell should be babbitted immediately after tinning. Babbitt should not be used for tinning, because it has a much higher melting point, which makes it difficult to maintain a molten film on the surface to be tinned. Cast-iron shells are rarely, if ever, tinned.

To avoid blow-holes and defects in babbitt linings, it is the practice of the Westinghouse Electric & Mfg. Co. to cover the mandrel with a thin coating of clay wash by plunging it, while heated, into a pail of water containing, in solution, one or two pounds of Jersey red clay. When the mandrel is dry, the thin clay coating prevents the formation of bubbles, and the lining has a smooth surface. Oil causes the babbitt to blister. When babbitting solid bearings, it is the practice in some shops to smoke the mandrel or cover it with paper to facilitate its removal from the bear-

Miscellaneous Bearing Metals

The following alloys are stated to have given complete satisfaction for the purposes mentioned:

ing. For two-part bearings, this is not necessary. Before pouring, babbitt should be stirred thoroughly to insure a lining of uniform composition. Whenever practicable, the bearing should be in a vertical position while pouring. The ladle should have a rounded spout rather than one which is sharp or broad. A broad thin stream, or one that is intermittent, tends to produce porous areas or blow-holes. Putty is preferable to clay for luting or sealing the ends of the bearings, as the moisture in the clay tends to cause sputtering.

Ball and Roller Bearings

Ball bearings are used in preference to sliding bearings principally for the following reasons: There is less loss of power on account of the lower coefficient of friction; the friction of a ball bearing is independent of the viscosity of the lubricant or its temperature; the frictional resistance at starting is very much less than in a sliding bearing; ball bearings are much shorter and more compact than sliding bearings; the scraping and fitting of bearing linings is not necessary; the danger of heated bearings is practically eliminated; a bearing of proper construction can adjust itself to deflections of the shaft; the wear is practically negligible.

Steel for Balls. — In order to determine the best steel for ball bearings, one of the largest elevator companies in the United States tested, by actual use, 432 different samples of steel obtained in this country and abroad. These tests indicated that the two grades of carbon and alloy steels given herewith are especially adapted for making steel balls:

Carbon, 1.12; silicon, 0.015; phosphorus, 0.017; manganese, 0.19; sulphur, 0.019; chromium, 0.25 per cent.

Carbon, 0.95; silicon, 0.014; sulphur, 0.019; phosphorus, 0.018; manganese, 0.025; chromium, 1.25; tungsten, 0.25 per cent.

Testing Strength of Steel Balls. — The testing of a steel ball for crushing strength can be done between hardened plates by placing three balls into a rather close-fitting tube. The center ball is the one that will be tested. When the pressure is applied, the upper and lower balls will sink into the plate somewhat, which will give them a greater surface bearing than the middle ball, the latter bearing only at two points between the upper and lower balls; hence, the middle ball will ordinarily break first. If a ball is properly hardened, it will break into several pieces. Uniformity of hardness throughout the entire cross-section and a fine grain are important qualities, both of which can be determined by the appearance of the fracture. Of course, the heat-treatment must be governed by the nature of the material. The accompanying table gives the crushing loads ordinarily required by ball manufacturers for regular tool-steel balls. The figures in this table are the result of repeated tests and are considered safe for use in calculations. In selecting balls for a bearing, a factor of safety of 10 should be adopted unless the bearing is required in an extremely narrow space. The loads listed by makers for ball bearings vary considerably and when the bearings are much alike in regard to size, design and material, this difference is due to the factor of safety adopted. Alloy steel balls will usually carry from 25 to 50 per cent more load than ordinary tool-steel balls.

Crushing Loads for Tool-steel Balls

Size of Ball, Inches	Ultimate Strength, Pounds	Size of Ball, Inches	Ultimate Strength, Pounds	Size of Ball, Inches	Ultimate Strength, Pounds	Size of Ball, Inches	Ultimate Strength, Pounds
1/16	390	1/4	6,215	5/8	39,000	1 1/8	125,000
3/32	875	5/16	9,940	3/4	56,250	1 1/4	156,000
7/64	1562	3/8	14,000	13/16	66,000	1 1/2	225,000
1/8	2450	7/16	19,100	7/8	76,000	1 5/8	263,000
3/16	3496	1/2	25,000	15/16	88,000	1 3/4	306,000
7/32	4780	9/16	31,500	1	100,000	2	400,000

Test of Heat-Treatment. — In order to determine whether a ball has been properly heat-treated, enclose the finished ball in a piece of waste, place it on an anvil and break it open with a heavy blow. (The waste prevents the pieces from flying about.) If the ball has been properly heat-treated, the surface of the fracture will have a fine even grain. If it has not been properly heat-treated, the surface will appear coarse and granular. Tests have shown that the average crushing load of balls that were annealed before hardening is approximately 30 per cent greater than of balls which were not so heat-treated. The heat-treatment not only strengthens the balls but prevents them from flaking off, crumbling, etc. If during the test the ball should break in half, it would indicate that the steel had not been properly drawn after hardening, but was still subjected to internal stresses. If a ball has been properly drawn, it can be "touched" with a fine Swiss file; and under the blows of a heavy hammer, it will break into several pieces, as mentioned.

Quality of Steel Balls. — Nothing but tool or alloy steel balls should be used for high-grade work, and it is very important that they be accurate as to size and shape and be properly heat-treated to obtain a fine grain. The material of which they are made should have as high an elastic limit as possible. Case-hardened machine steel balls should not be used when heavy duty is required. While a ball can be case-hardened very deeply, the process does not remove the injurious elements, phosphorus, sulphur and silicon, which the cheaper steels contain in comparatively large percentages. Case-hardened balls have, however, proved satisfactory for many purposes, where the duty is not too severe.

Lubrication of Ball Bearings. — Ball bearings require lubrication and should never be run dry. The actual lubricating property of the lubricant used is not as important as its freedom from acid and its effectiveness as a preventative of rust. A very small quantity is sufficient for lubrication, but it is advisable to use a comparatively large supply to prevent rust. If an acid oil is used, the finely finished surfaces of the balls and races will be etched or pitted and the efficiency of the bearing seriously affected. Free acid is not found in properly refined mineral or hydrocarbon oils; hence mineral oil should be used instead of vegetable oils, such as castor, cotton-seed, rape and linseed oils, which tend to develop acid and become gummy and rancid. Animal oils are objectionable for the same reasons. A mixture of vaseline and vaseline oil, or a good mineral oil is recommended. To test the neutral quality of a lubricant, soak some threads of waste in it and wrap them around a clean piece of polished steel; then expose directly to the sun's rays, in a warm place. A good oil or grease will show no signs of etching after months of exposure, but an acid oil will discolor the steel and show signs of impairing its finished surface within a few days. A period of one or two weeks is long enough to determine definitely the nature of the lubricant. In general, greases are recommended for speeds up to 2000 or 2500 revolutions per minute. When a high speed and resulting increase in temperature causes the grease to thin out, oil should be substituted. Ordinarily, grease is preferable because it can be more easily retained in the bearing case. A grease should be used that does not contain free alkali, as the latter will pit or etch the polished steel surfaces the same as acids in oils.

Mounting Ball Bearings. — In the mounting of ball bearings, there are certain requirements which apply generally, although the exact arrangement must be governed to some extent by the conditions. If the bearing is to carry a radial load without thrust, the inner race should have a light driving fit on the shaft and be securely clamped against a shoulder by a nut or clamping device which is proof against jarring loose. The outer race of a bearing subjected to a radial load only, should fit closely in its retaining box or housing, but be free to "float" or shift in an endwise direction. When the outer race is mounted in this way, it will align itself with reference to the inner race and will tend to have a slow intermittent creeping movement, insuring a proper distribution of the load over the entire surface of the outer race. Even when it is desired to prevent end motion of the shaft, a slight lateral clearance of 0.010 or 0.015 inch should be provided, to permit the creeping movement and prevent the load from always bearing in one position on the race. When mounting for combined radial and thrust loads, the outer race of one bearing must be secured against endwise movement. If there are several radial bearings on the same shaft, the end thrust in both directions should be taken by the same bearing, and the outer races of the other bearings should be free to locate themselves. It is considered good practice when two bearings are mounted on one shaft, to prevent axial thrust by making the inner race of each bearing a light driving fit on the shaft. The outer race of one bearing has a sliding fit in its seat and is given a slight amount of axial play (say, from 0.010 to 0.020 inch); the outer race of the other bearing is also made a sliding fit, but is allowed considerable axial play. The first bearing takes the radial load and end thrust, and the second bearing, a radial load only. In selecting a bearing, it is well to remember that the rated capacity is usually for steady loads and speeds, and variations from these conditions require a reduction of the listed capacity. It is important to mount bearings so that they will be free from grit and moisture. If it is necessary to take ball bearings apart, the balls from different bearings should not be mixed, as they may vary in size more than is permissible for the individual bearing.

Thrust in Radial Bearings. — It is common practice to use the radial type of ball bearing when there is an axial thrust in addition to the normal radial load. Radial bearings, however, should not be subjected to end thrust when the speed of rotation is low, especially if the end thrust is great, as in automobile front wheels, etc. When ball bearings are used for such purposes, make the outer rims of the two bearings a sliding fit and allow them considerable axial play, so that they cannot possibly take end thrust. The thrust is then taken by a thrust bearing, usually placed between the radial bearings. If the speed of rotation is above 1200 or 1500 R.P.M., the thrust can be taken by a radial bearing, since at high speeds the radial type is superior to a regular thrust bearing. The following information regarding thrust loads on radial bearings is given by Mr. Henry Hess (see also *Proceedings of A.S.M.E.*, June, 1907). Theoretically, the radial bearing seems to be incapable of carrying a thrust load, owing to the wedging of the balls between the races. Actual running tests, however, as well as considerable experience, have demonstrated that radial bearings will carry much more thrust load than theoretical calculations indicate. It has been experimentally determined that the thrust carrying capacity of the uninterrupted type of radial bearings is to the radial capacity as 0.1 is to 1 and may be as great as 0.25 to 1, the variation depending upon the ball diameter, race curvature and number of balls. Tests have also shown that for speeds above 1500 revolutions per minute, radial bearings are more efficient thrust bearings than the collar type. In selecting a radial ball bearing to take both thrust and radial loads, the Hess-Bright Mfg. Co. advises that 10 pounds of rated radial capacity should be allowed for each pound of thrust load. For thrust and radial loads of 150 and 1500 pounds, respectively, select a bearing rated at $150 \times 10 = 1500$ pounds, for the thrust, and 1500 for the radial load, or a total rated radial capacity of 3000 pounds. For speeds less than 1500 revolutions per minute, and for heavy duty, a thrust and radial bearing combination is preferable.

The S. K. F. radial bearings are designed to carry approximately 25 per cent of their rated radial load as pure thrust. For combined radial and thrust loads on a single radial bearing, the allowable thrust may be calculated in accordance with the following formula, in which P = total load; T = thrust load; R = radial load.

$$P = 4T + R$$

Under these conditions, P should, in no case, exceed the allowable rating for the bearing. In many instances, exact load conditions are indeterminate and due allowance should be made for shocks or rapidly changing load conditions. It is well to obtain information regarding the form of bearing, mounting, capacity, etc., directly from the manufacturers, especially when the conditions are unusual.

Ball Thrust Bearings. — Thrust bearings are adapted for heavy axial loads. They are made with both races flat on the bearing side; with one race flat and the other grooved; and with both races grooved. A form that is commonly used has two grooved races of circular section, and a spherical seat for one of the races or collars, so that the latter will align itself in order to distribute the load evenly over the entire number of balls. Some bearings of the thrust type have both of the outer thrust surfaces parallel. With this design, the collars should be exactly parallel, so that the load will be uniformly distributed on the balls. In fact, when two flat disks without the spherical seat are used, the capacity of the bearing depends largely upon the accuracy of the alignment, because, with even a slight distortion of the shaft, the load will not be sustained by the total number of the balls. When mounting single thrust bearings, the flat disk should properly have a tight fit on the shaft and rotate with it, the spherical seat remaining stationary, except for adjustments to compensate for changes in shaft alignment.

Capacity of Ball Thrust Bearings. — The speed at which thrust bearings are run, decidedly affects the carrying capacity, the latter rapidly diminishing as the speed increases. The centrifugal force at comparatively high speeds is the limiting feature in a bearing of this type. A general idea of the maximum loads which thrust bearings will carry at different speeds may be obtained from the accompanying tables.

Frictional Resistance. — Extensive tests for determining the coefficients of friction for various types of ball bearings show that the coefficient varies between close limits at different loads and speeds, whereas, for sliding bearings, it extends over a wide range for even small changes in speed or load. The frictional resistance of ball bearings has by actual experiment been found to vary between 0.0011 to 0.0095. These are the coefficients of friction referred to the shaft diameter, thus permitting direct comparison with coefficients of sliding friction. Ball bearings having a coefficient of friction much above 0.0015 under the greatest allowable load should not be recommended, because they are too short-lived. A coefficient of 0.0015 for a good ball bearing under its maximum load (independent of the speed, within limits) will, however, rise to approximately 0.0030, under a reduction of the load to about one-tenth of the maximum.

Loads on Ball Bearings. — The permissible load that a two-point annular ball bearing will carry can be determined approximately by the following formula (based upon the investigations of Prof. Stribeck), after a suitable value has been determined for constant K:

$$P = 0.44\,Kd^2n$$

in which K is a factor, depending upon the material in the balls, the form of the ball races and the operating speed of the bearings; n equals the number of balls; and d their diameter, taking ⅛ inch as the unit; for example, if the actual diameter is ¼ inch, d equals 2; if the diameter is ⅝ inch, d equals 5, etc. The better the material and the more careful the heat-treatment, the greater the value of factor K. When the diameter of the balls is increased, the value of K is decreased, as it is more difficult to harden a large ball uniformly, than a small one. With regard to the rotary speed, K should be diminished as the number of revolutions increases. For ball bearings made of high-grade material and accurately machined, K has the following approximate values for steady loads and uniform speeds:

Revolutions per Minute......	10	150	300	500	1000	1500
Values of K................	20	18	15	10	7.5	5

The preceding formula should be sufficiently accurate for bearings in which the balls vary from 10 to 20 in a set, provided the balls and races are properly proportioned. If a bearing had a comparatively large number of balls of such diameter that the strength of the races was impaired, the formula would indicate a greater load capacity than the bearing could safely carry. Even when the formula is applicable, which, as has been indicated, is only within certain limitations, it will sometimes be found that a bearing having a larger number of smaller diameter balls may be stronger than one with a less number of a larger diameter, or *vice versa*. The difference between the relative capacities may also be greater than the formula indicates, as the conditions of loading are more advantageous in a bearing having a greater number of smaller balls.

Ball-circle Diameter for Ball Bearings. — When the number and size of the balls and the space required between consecutive balls are known, the ball-circle diameter can be found by the formula: $D = C(d + S)$, in which D = ball-circle diameter; d = ball diameter; S = space between balls; and C = a constant taken from the accompanying table. (The distance S is measured on a straight line joining the centers of adjacent balls.)

Example: — If the required number of balls is 17; the diameter, 5/16 inch; and the space between the balls, 1/8 inch, what is the ball-circle diameter D?

Referring to the table, opposite 17, in the column headed "No. of Balls," the value of constant C is found to be 5.4422. Substituting known values in the formula, $D = 5.4422\ (5/16 + 1/8) = 2.381$ inches = diameter of ball circle.

Roller Bearings. — A long series of tests with various types of roller bearings indicate that while each type has its peculiarities, there are certain principles which apply quite generally within narrow limits. The coefficient of friction of roller bearings is greater at low than at high speeds, but is much more nearly constant than in plain lubricated bearings. The coefficient of friction in bearings in which there is pure rolling is nearly constant at all speeds, but when there is end thrust, the friction decreases as the speed increases. The coefficient of friction is indepen-

The above rating is for steady loads and speeds, and fifty per cent temporary overload capacity can be added. For varying loads and speeds the relative value of load and overload must be modified. Both races of Norma Roller Bearings must be rigidly held endwise. The rollers are cylindrical; the inner race is ground cylindrical, and the outer race, instead of being flat, is ground to a slightly convex surface.

* The Norma Company of America

dent of the temperature of the bearings, unless the end thrust is excessive. The friction in a well-designed bearing is not greatly affected by lubrication. The wear of the rollers is often excessive, if the rotating parts and the casing are not hardened and well finished, especially when the bearing is subjected to end thrust. The end thrust on the rollers varies almost directly as the load on the bearing and usually diminishes as the speed increases. The direction of the thrust is usually reversed when the direction of rotation is reversed.

* This table gives the load capacities of Hyatt roller bearings with rollers operating directly on shafts. The loads are based on the use of steel containing from 0.40 to 0.50 per cent carbon with a hardness of 165 Brinell or 25 scleroscope for split outer races, and 600 Brinell for solid outer races. For other degrees of hardness the loads given in the table should be multiplied by a suitable hardness factor (see end of table on following page). When the required shaft hardness cannot be obtained a bearing having a hardened solid inner race is used.

Example: — Determine the load capacity of a 2- by 4-inch bearing having a *split* outer race, assuming the speed is 300 R.P.M. and the shaft hardness 250 Brinell.

The load capacity given in the preceding table is 900 pounds which is based on a hardness of 165 Brinell. The hardness factor for 250 Brinell is 1.5 for a split outer race; hence the load capacity equals 900 × 1.5 = 1350 pounds.

Loads on Roller Bearings. — The safe load diminishes as the speed of rotation of the rollers increases. If the speed is not excessive, the safe load may be determined approximately by the following formula: $P = \frac{Klnd^2}{ND + 2000\,d}$ in which P = safe load, in pounds; l = length of each roller, in inches; n = number of rollers; d = diameter of rollers, in inches; N = revolutions per minute of shaft; D = diameter of sleeve or roller path, in inches; K = a constant. For first-class workmanship and solid steel rollers with hardened and ground surfaces, K = 1,200,000 to 2,000,000, for rollers having a length equal to one diameter.

Bearing Lubricants

Classes of Lubricants. — Lubricants are derived from mineral, vegetable and animal sources. *Mineral Oils:* Nearly all commercial lubricating oils are obtained from petroleum, although some mineral oils are also derived from shale. Mineral oils are classed commercially as "pale" and "dark." The pale oils are somewhat transparent and are tinged with a variety of yellow and red shades. The dark oils are opaque and are either greenish- or brownish-black. The specific gravity of mineral oils usually varies from about 0.860 to 0.940, and the flashing point, from 300 to 600 degrees F. The oils obtained from petroleum have a much wider range of viscosity than the "fixed oils." The thinnest are more fluid than sperm oil, and the thickest more viscous than castor oil. The shale lubricating oils are of low viscosity. *Fixed Oils and Fats:* Fixed oils are so named because they are not volatile without decomposition. They are obtained from the seeds or fruits of plants and the tissues of animals. All fixed oils become fats at low temperatures and, inversely, all fats become oils at 150 degrees F. The most common lubricants among animal oils are tallow, lard, neat's foot and sperm oil, and among vegetable oils, olive, rape and castor oil. Ordinarily, animal oils are either colorless or yellow, whereas vegetable oils have various shades of yellow and green. The specific gravity of fixed oils varies from about 0.879 to 0.968 at 60 degrees F. Sperm oil has the lowest viscosity and castor oil the highest. *Blown or Thickened Oils:* Lubricants of this class are fixed oils (usually rape or cotton-seed) which are artificially thickened by forcing a current of air through the heated oil. This process increases the density and viscosity. Blown oils mixed with mineral oils are very largely used as lubricants. The mineral oils used for this purpose are usually of rather low viscosity. *Rosin Oil:* This oil is obtained from common rosin by distillation, and is not suitable for the lubrication of machinery, but is used to adulterate mineral and other lubricating oils. *Soap and Grease Lubricants:* Some mineral oils are thickened artificially by the addition of a substance such as aluminum soap. This increases the viscosity, but the latter rapidly diminishes when the oil is heated. Mineral oils are also thickened with sufficient soap (such as lime, soda or lead soap) to form a grease at ordinary temperatures. These greases may also contain some solid lubricant, such as graphite, talc, etc. *Adulterants:* Many of the more expensive oils, such as sperm, olive and lard, are adulterated with cheaper fixed oils and mineral oils. Cotton-seed is often mixed with lard and olive oils, and is sometimes substituted for the latter. The use of adulterants in order to increase the viscosity is usually resorted to in the case of mineral oils. The presence of these adulterants can sometimes be detected by comparatively simple tests. (See "Testing Lubricating Oils.")

How Lubricants are Affected by Use. — Experiments have been made to determine whether or not lubricating oil "wears out" in long continued service. These tests were made at Cornell University and indicated that oil gains in specific gravity by continued use, on account of the loss of volatile constituents. The used oil has a higher viscosity than new oil, indicating that it gains in "body" with use. Friction tests showed that new oil has a slightly lower coefficient of friction at low bearing pressures, but the reverse is true for high pressures. The differences, however, are so small that the coefficient of friction may be considered equal for new and old oils.

Qualities and Properties of Lubricants. — Although animal and vegetable lubricants differ from mineral lubricants chemically, many of the physical properties are similar. Of these properties, viscosity and "oiliness" are the most valuable. The viscosity of a particular animal or vegetable oil does not vary greatly in different samples, but mineral oils have a wide range of viscosity, and the required degree of fluidity must be considered in selecting a mineral lubricant.

The viscosity of all lubricants varies considerably with changes of temperature. For instance, an oil might be sufficiently viscous to carry a given load under normal conditions, but become so fluid, due to a rise in temperature, as to cause the bearing surfaces to cut and abrade each other. The viscosity of mineral oils varies more with the temperature than the viscosity of fixed oils; hence a bearing lubricated with a mineral oil needs more attention than one lubricated with a fatty oil.

Blended Oils: Mineral oils possess valuable properties which are conferred upon other lubricants with which they are mixed; as they are also a great deal cheaper than good fixed oils, blended or mixed oils are commonly used. The percentage of mineral oil that should be added varies according to the load, speed, etc., because many mineral lubricants are deficient in the property known as "oiliness" and can seldom be used pure, except when the bearing is kept flooded with oil by bath, ring or forced lubrication. Pure mineral oils are quite satisfactory for forced lubrication, and must be employed for lubricating the cylinders of condensing engines, because fixed oils would be likely to enter the boilers and cause damage. In general, fixed oils (if of sufficient viscosity) and fats are adapted for comparatively high bearing pressures, and mineral oils, for light pressures. The speed should also be considered, viscous oils giving the best results at low speeds, and thin oils, at high speeds. The viscosity, however, even at low speed, should be as low as possible to prevent excessive friction. Pressures below 70 pounds per square inch may be regarded as light, and speeds below 100 feet per minute, as low speeds. Pure mineral oils may be used for pressures below 70 pounds per square inch, with free lubrication, provided the bearing metals are such as do not readily "seize" each other. As the bearing pressure increases, the proportion of fixed oil should also increase.

Fats and Greases: It may be said, in general, that the lubricating properties of a mineral grease like vaseline, and an animal fat such as tallow, differ just as in the case of mineral and fixed oils, the animal fat possessing in a much greater degree the property of greasiness. Many lubricating greases are made by incorporating or emulsifying animal and vegetable fats with soap and water, or by thickening mineral lubricating oils with soap. These lubricants are often used with good results for railway car axles and the bearings of slow-moving machinery. If the bearing loads are exceptionally heavy, solids such as plumbago and soap-stone are sometimes added to the grease. Except in special cases, grease should not be used for fast-running journals, because the increased frictional resistance results in great loss of power. It is only when the surface speeds of bearings are low that economy results from the use of greases. Very satisfactory results, however, have been obtained by the use of grease for locomotive lubrication.

Gumming: Many oils when exposed to the atmosphere in thin films (as on bearings) form gummy masses, which clog the moving parts and cease to act as lubricants. A high temperature increases this tendency; hence gumming oils such as rape should not be used in warm places. (To clean surfaces which are covered with a gummy oxidized lubricant, the parts should be well moistened with paraffin oil.)

Foreign Substances: When bearings become heated, first ascertain definitely whether the fault really lies with the lubricant or is due to impurities accidentally produced. Bearings sometimes become heated when an excellent quality of lubricant is being used, and this is often due to the presence of foreign elements such as sand, vegetable fiber, etc.

It is well to remember, when selecting a lubricant, that a cheap oil will often result in greatly increasing other expenses; hence quality and adaptability for the surface required are the most important considerations.

Lubricants for Heavy Loads and Low Speeds. — The relative carrying capacity of oils, greases and solid lubricants can be determined only approximately, and the selection must finally be governed by actual trial, in order to secure a lubricant which gives a minimum amount of heating and friction. Four classes of lubricants for low speeds and comparatively high pressures are referred to in the following: 1. Graphite, soap-stone and other solid lubricants used dry. This class has the greatest carrying power, and the efficiency of the lubricant depends largely upon the nature of the bearing surface. Graphite, for example, gives the best results on cast-iron surfaces. 2. Solid lubricants mixed with animal fats, greases, vaseline, etc., or rosin grease. These mixtures are adapted for heavy work, especially when metal works against wood. 3. Axle grease composed entirely of animal and vegetable fats, or mineral oils emulsified with water, soap and enough alkali to make them neutral. These greases are excellent for slow-moving shafts and journals subjected to considerable loads. 4. Fixed oils, mineral oils and mixtures of the two. In selecting oils for low speeds and high pressures, viscosity must be the first consideration and, next to that, oiliness. If the viscosity is high enough, mineral oil may be as good as or even better than a fixed oil; or a mixture may be preferable to either.

Lubricants for Moderate Speeds. — Mineral oils are excellent for bearings subjected to comparatively light loads and running at moderate speeds. In general, the viscosity should increase as the speed of rotation diminishes. This applies particularly to mineral oils. As the loads increase, wear and overheating may result unless fixed oils be added, although it is rarely necessary to use pure fixed oils. For locomotives, 75 per cent mineral oil and 25 per cent rape oil has been found satisfactory. The necessity for using expensive fixed oils instead of the cheaper mineral oils is sometimes due to imperfect lubricating devices. When selecting a lubricant for bearings operating at ordinary speeds, viscosity is the most important property to consider, provided the loads do not exceed 200 to 250 pounds per square inch.

Lubricants for High Speeds. — High-speed bearings for armature shafts, etc., require thin lubricating oils. If ample bearing surface has been provided, thus reducing the unit pressure, pure mineral oils can be used to advantage. When good lubrication is impossible, it may be necessary to use some fixed oil. A mineral oil containing about 10 per cent fixed oil, gives little frictional resistance and minimizes wear.

Lubricants for Different Classes of Machinery. — A mixture of mineral oil and from 10 to 20 per cent neutral animal or vegetable oil is suitable for bearings of *machine tools*, *shafting*, and all machinery of medium weight and speed. Animal oils are usually preferable to vegetable, as they are less liable to gum. The heavier the machine and the slower the speed, the greater the viscosity required. For *dynamos* and *motors* with bath or ring lubrication, use mineral oil (preferably pure) having from two-thirds to about three times the viscosity of rape oil at 60 degrees F., depending upon the size, weight and speed of the machine. For *ball bearings* and *chains* for motor vehicles, etc., a neutral animal oil or fat, either pure or mixed with a fairly viscous mineral lubricating oil, is the most suitable. For the *chain* of a bicycle or motor, use a good grease or fatty oil. Good results are obtained by running the chain through a bath of sperm oil, or a mixture of good mineral oil and a little refined animal oil. Except when an oil bath is used, a thick oil or grease is necessary, as a thin lubricant runs off rapidly. For *light, delicate machinery* running at fairly high speeds, use mineral lubricating oil having about the same viscosity as sperm oil, and preferably mixed with 10 to 20 per cent sperm oil. For *pneumatic hammers*, use a good quality of light mineral oil, as a heavy oil tends to clog the parts. The ring spindles of *textile machinery*, running in an oil bath at speeds as high as 10,000 revolutions per minute, should be lubricated with a mineral oil of low viscosity not exceeding that of sperm oil at 60 deg. F. For *turbine bearings* having forced or circulating-pump lubrication, use pure mineral oil having a viscosity of from one to five times that of refined rape oil at 60 degrees F., depending upon the bearing pressure, speed and temperature conditions. For *high-speed engine bearings* having forced lubrication, use pure mineral oil of about twice the viscosity of rape oil at 60 degrees F. For *steam engine cylinders*, use heavy mineral cylinder oils mixed with from 5 to 25 per cent of rape or other fixed oil, the proportion of the latter being reduced as low as possible without impairing the lubricating quality. Sometimes pure mineral oil must be used in the cylinders of marine and other engines provided with surface condensers, to prevent fixed oils from entering the boiler. Vegetable and animal oils are unsuitable for cylinder lubrication, because when subjected to high temperatures they undergo a chemical change, resulting in the formation of free, fatty acids which may cause serious corrosion. Fatty oils, however, when mixed with mineral oils in quantities not exceeding from 5 to 20 per cent, do not seem to produce these objectionable results. For *locomotive axles*, use mineral oil having from two to four times the viscosity of rape oil at 60 degrees F., mixed with refined rape oil in the proportion of three parts mineral to one part rape. For very *heavy locomotives*, especially in warm climates, it is desirable to increase the viscosity of the mixture by adding some good mineral cylinder oil. For *bearings working in hot places*, use mineral oil to which is added from 20 to 33 per cent blown or thickened vegetable oil (usually rape). For *gas engine cylinders*, a mixture of 90 per cent mineral oil and 10 per cent neutral fixed oil is largely used. The viscosity is about the same as that of rape oil at 60 degrees F. As carbonaceous deposits are liable to form in the cylinder by partial combustion of the lubricant, especially when used in excess, the mineral oil selected should have undergone very careful rectification, and have little tendency to decompose and deposit carbon when heated. They should also be oils of low volatility, not being affected appreciably by evaporation at working temperatures.

Over-heated Bearings. — An over-heated bearing may be due to a number of different causes, such as incorrect design of bearing, use of an unsuitable lubricant, or improper method of applying the lubricant. When a bearing suddenly becomes heated, it is advisable to immediately apply a fatty oil of good quality, as the viscosity of an oil of this kind does not diminish with the rise of temperature to the same extent as with a mineral oil; moreover, the fixed oils are more "oily." Rape or olive oils are good for such emergencies. Sometimes a bearing runs hot because it has been without oil for a short time. When it is not feasible to stop the rotating part (as in the case of marine engine bearings) it is common to turn a stream of clear or soapy water upon the heated part. Sometimes serious damage can be prevented by throwing plumbago upon the journal or by applying the plumbago mixed with oil. When a bearing which has run cool (thus showing that the design is not at fault) repeatedly becomes heated, it should be taken apart and be examined carefully. The boxes may be adjusted too closely, the journal may be out of true, or the bearing surfaces be scored or grooved. Sometimes a surface crack in a bearing will cause heating, because it intercepts the oil film and allows the lubricant to escape. If the bearing is apparently in good order, the lubricant may be the cause of the trouble. If the viscosity is too low, the oil film does not form properly and there is direct contact between the rubbing surfaces. A bearing also tends to become heated if the viscosity of the oil is too high.

Testing Lubricating Oils. — The quality and properties of some lubricating oils can be determined approximately without the use of special testing apparatus by the following simple methods: To determine the presence of solid impurities in the oil, kerosene is added to half a tumbler of oil until the whole becomes quite thin. The mixture is then passed through filter paper or ordinary white blotting paper, and after all the oil has passed through, the paper is washed with kerosene; the residue on the paper, if any, will show if the oil had any solid impurities. Impurities may also be roughly detected by smearing a piece of writing paper with oil and holding it against the light; if the oil is free from solid impurities the blot will be equally transparent throughout — otherwise, the solid particles will show. The oil must not resinify: To test it in this respect, pour into a shallow dish and leave in a warm place about a week. There must not be the slightest crust at the end of that time.

Another way to test oil is by mixing it with fumes of nitric acid: If the oil is pure, a thick mass will form in a few hours, while resinifying oil will remain thin. Acids are very injurious impurities in lubricating oil, since, in time, they attack the machine parts lubricated. To test for acids, copper oxide or copper ash is added to the oil in a glass vessel; acid-free oil retains its original color, while, if it contains acid, it becomes greenish or bluish. Another test is to drop the oil on a sheet of copper or brass and leave it there for a week; if the oil contains acid there will be a green spot on the metal. A good oil must be greasy in order to have good lubricating qualities; to find which of several oils is best in this respect, place a few drops of the different oils on a smooth, slightly inclined metal or glass sheet; the drop of the best oil will travel furthest in a given time.

Cylinder oil may be tested by heating it and noting its color. A good cylinder oil will not change color to any noticeable degree, when heated to 480 degrees F., or to a temperature higher than that existing in a high-pressure engine cylinder. Low-grade oils, however, will darken when heated to this temperature. Another method of testing cylinder oils which gives good results is as follows: Heat the oil in a current of air for one hour, at a temperature corresponding to that of the required steam pressure. The loss in weight should not exceed 0.5 per cent.

Lubricants for Lathe Centers. — The following lubricants are recommended for lathe centers to prevent cutting or abrasion: 1. Dry or powdered red lead mixed with a good grade of mineral oil to the consistency of cream. 2. White lead mixed with sperm oil with enough graphite added to give the mixture a dark lead color (when necessary, thin by adding more oil). 3. Graphite one part and tallow four parts, the two ingredients being thoroughly mixed.

Rust Resisting Grease for Nuts. — When nuts, wash-out plugs, etc., are lubricated to prevent corrosion and facilitate their removal after a long period, a lubricant should be used which does not evaporate, and which does not corrode or otherwise injure the metallic surfaces. Use a lubricant consisting of thick mineral cylinder oil, or petroleum jelly mixed with black lead. Do not use tallow or any fat oil or grease, as fat soon undergoes a change and allows the thread surfaces to corrode. A thin mineral oil is also unsuitable as it soon flows out of the joint and evaporates. Sometimes there should be no lubricant, especially if the nuts are subjected to vibration which tends to loosen them, as the nuts of rail fish-plates, etc.

Protection of Finished Surfaces. — The finished or polished surfaces of machinery can be protected from rust by applying (while warm) a mixture of white lead and tallow, this being very commonly used. Neutral petroleum jelly is also a good rust preventive for steel, provided the surfaces to which it is applied are perfectly dry. To prevent the rusting of tools stored in the stock-room, etc., a coating of what is known as "cosmolubric oil No. 1" will be found very effective. If the oil becomes too thick, heat it slightly. Another good rust preventing lubricant is made from equal parts of turpentine and linseed oil. Machinery that may be exposed to rain or considerable moisture while being exported can be protected by coating the surfaces with black enamel or japan.

KEYS AND KEYWAYS

Dimensions of Sunk Keys. — Keys are generally proportioned with relation to the shaft diameter, instead of considering the torsional load in each case, because of practical reasons, such as standardization and interchangeability. There are, however, no fixed standards among manufacturers, although a fair idea of the average practice can be obtained from the following rules which apply to sunk keys:

Rule 1. The key width equals $\frac{1}{4}$ of the shaft diameter; the thickness, $\frac{1}{6}$ of the shaft diameter; the minimum length, $1\frac{1}{2}$ times the shaft diameter. Expressing these rules as formulas:

$$W = \frac{D}{4} \qquad T = \frac{1}{6}D \qquad L = 1.5\,D$$

in which W = key width; T = key thickness; L = key length; and D = shaft diameter. This notation is also used in the following formulas:

Rule 2. $W = \frac{3}{16}D + \frac{1}{16}$ inch; $T = \frac{1}{8}D + \frac{1}{8}$ inch; $L = \frac{3}{10}D^2 \div T$

For splines or feather keys, interchange the dimensions for width and thickness.

Rule 3. (Unwin.) $W = \frac{1}{4}D + \frac{1}{8}$ inch; $T = \frac{1}{8}D + \frac{1}{8}$ inch.

When gears or pulleys transmitting only a small amount of power are keyed to large shafts, these dimensions are excessive. In such cases, if P = horsepower transmitted by the gear or pulley; N = revolutions per minute; F = force in pounds acting at circumference; and R = radius of pulley in inches, then:

$$D = \sqrt[3]{\frac{100\,P}{N}} \quad \text{or} \quad \sqrt[3]{\frac{FR}{630}}$$

The taper of sunk keys is usually about $\frac{1}{8}$ or $\frac{3}{16}$ inch per foot. The depth of a taper keyseat at the deep end should be $\frac{3}{5}$ of the key thickness.

Proportions of Sunk Keys (U. S. Navy Standard)

Diam. of Shaft	Width of Key	Thickness of Key	Diam. of Shaft	Width of Key	Thickness of Key	Diam. of Shaft	Width of Key	Thickness of Key	Diam. of Shaft	Width of Key	Thickness of Key

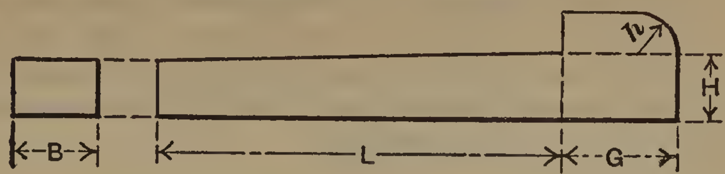
Propeller Keys. — The practice of the U. S. Navy in proportioning keys for propellers is to make the width of the key about 1½ times its thickness. The thickness, in turn, is so determined that the side pressure on the propeller hub, calculated

Dimensions of Gib Keys



Keys of proportions given below are weakest in shear.
The safe twisting moment per inch of length of keys = $R \times B \times S$

- R = radius of shaft;
- B = breadth of key;
- S = safe shearing strength of material in key;
- B = ¼ times diam. of bore, up to 6 inches; for larger sizes, $B = 0.211 \times$ bore, approximately;
- $G = B$, approximately;
- H = ⅙ times diam. of bore up to 6 inches; for larger sizes, H = ⅛ $\times$ bore;
- h = radius = ⅛ times diam. of bore, approx., but minimum value = 3/16 inch;
- L = length of hub + ½ inch.

Taper ⅛ inch per foot.

Bore and Shaft Diameter	Width of Key B	Height of Key H	Depth of Key-way $\frac{H}{2}$	Rad. h	G	Safe Twisting Moment on Key per Inch of Length f or S = 5000	7500	10,000

from the maximum turning moment on the shaft, does not exceed 25,000 pounds per square inch. Ordinarily, the key is so proportioned that the pressure on the keyway will not exceed 22,000 pounds per square inch. With this pressure, if the key thickness is over $\frac{1}{8}$ of the shaft diameter, two keys set opposite are preferred. The hub of the propeller is bored, tapered and fitted to a corresponding taper on the shaft, which is provided with a retaining nut.

Dimensions of Flat Keys

Woodruff Keys. — Woodruff keys are used extensively in machine tool construction. They should project above the shaft a distance equal to one-half of the thickness. The accompanying tables give the proportions of the regular standard and also the special Woodruff keys. When using the table which indicates the sizes of keys that are best adapted to different shaft diameters, where more than two keys are given for a certain diameter, the medium size key should be used in ordinary practice.

When milling the shaft to receive a Woodruff key, the shaft is brought against the cutter until a flat of the same width as the thickness of the cutter is formed; the cutter is then fed into the shaft to the required depth. If the keyseating cutter should cut a little large, the size of the cutter may be reduced slightly by holding an oilstone against the face of the revolving cutter. Care should be taken to eliminate all end-play in the spindle of the machine. When fitting a Woodruff key, the edges and corners should be "brushed" slightly with a file to insure the key entering readily.

Standard Woodruff Keys to Use for Different Shaft Diameters

Diameter of Shaft	Number of Keys	Diameter of Shaft	Number of Keys	Diameter of Shaft	Number of Keys
5/16 –⅜	1	⅞ – 15/16	6, 8, 10	1⅜ –1 7/16	14, 17, 20
7/16 –½	2, 4	1	9, 11, 13	1½ –1⅝	15, 18, 21, 24

* Use cutters Nos. 26, 27 and 28 for keys Nos. 126, 127 and 128.

Cotters. — A cotter is a form of key that is used to connect rods, etc., that are subjected either to tension or compression or both, the cotter being subjected to shearing stresses at two transverse cross-sections. When taper cotters are used for drawing and holding parts together, if the cotter is held in place by the friction between the bearing surfaces, the taper should not be too great. Ordinarily a taper varying from ¼ to ½ inch per foot is used for plain cotters. When a set-screw or other device is used to prevent the cotter from backing out of its slot, the taper may vary from 1½ to 2 inches per foot.

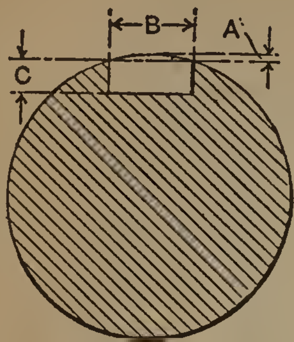
Pratt & Whitney Co.'s System of Keys. — A system of round-end feather keys has been developed by the Pratt & Whitney Co., and is used in their plant. The system is also being adopted by many other manufacturers. The keyways are milled by means of a spline milling machine made by the company. The dimensions given in the table are those used in the Pratt & Whitney works. The numbers of the keys correspond to the numbers used for designating keys in the Woodruff system, and the dimensions are proportionately the same. The length *L* of the key, however, may vary from the length given in the table, but it should be equal to at least two times the width *W* of the key. The keys are made 0.001 inch over standard size in width to insure proper fitting in the keyway.

Friction of Sliding Keyways. — When a clutch moves along a shaft to which it is keyed, it is always preferable to use two keyways, one on each side of the shaft, instead of a keyway only on one side. Experiments have shown that when two keys are used, the frictional resistance of a clutch to sliding on the shaft is only one-half of what it is with one key.

Dimensions for Obtaining Depths of Keyseats



The values in the body of the table give the dimension *A*, which should be added to the depth *C* of the keyway in order to find the total depth from the outside of the shaft to the bottom of the keyway. When milling keyways, the cutter can be fed down this total depth, and no further measuring is necessary.

Size of Shaft	Width of Keyway *B*					Size of Shaft	Width of Keyway *B*

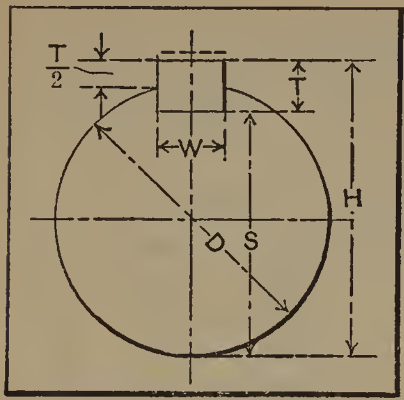
Gaging Depths of Keyseats. — The table, "Dimensions for Obtaining Depths of Keyseats" was compiled to facilitate the accurate milling of keyseats. This table gives the distance *A* (see illustration accompanying table) between the top of the shaft and a line passing through the upper corners or edges of the keyseat. Dimension *A* is added to the side depth of the keyseat to get the total depth from the outside of the shaft. To mill a keyseat, adjust the cutter until it just touches the top of the shaft, and set the dial of the elevating screw to zero; then sink the cutter to the total depth, which equals depth C at the side, plus distance A obtained from the table. For example, if the diameter of the shaft is 3 inches and the key width is ½ inch, 0.021 inch should be added to the depth C in order to get the total depth from the top of the shaft. The height A of the arc can be calculated by the following formula:



$$A = R - \sqrt{R^2 - (\tfrac{1}{2}B)^2}$$

in which A = height of arc; R = radius of shaft; B = width of keyseat.

Example: — If the shaft radius is 5 inches and the width of the keyseat, 2 inches, then:

$$A = 5 - \sqrt{5^2 - 1^2} = 5 - \sqrt{24} = 0.101 \text{ inch.}$$

A method of measuring keyseats, which reduces the amount of fitting to a minimum, is indicated by the accompanying illustration. The keyway in the shaft is measured for depth as indicated by S, and the keyseat in the hub is measured across the bore, as at H. The advantage of this method is that the space T between the shaft and the hub does not vary (provided the keyseats are accurately cut and gaged) even though there be slight variations between the shaft diameter and the bore of the hub. The dimensions H and S for various diameters of shafts are given in the table, "Dimensions for Measuring Keyseats Across Shaft and Bore of Hub." In compiling this table, the following rules were used: The key width equals the fractional size nearest ¼ of the shaft diameter, the fractions varying by 1/16 inch increments up to ¾ inch widths, then by ⅛ inch up to 1¼ inch, after which the advance is made by ¼ inch increments. The key thickness at the thin end equals ¾ of the width, and the taper is ⅛ inch per foot. Keys 1 inch wide and wider are made thinner than the foregoing rule calls for. The keyway depth in the hub and shaft are made approximately equal at the thin end of the key, and the depth in the hub is measured at the shallow end of the keyway. With this system, there is no necessity of varying the standard for an extra long hub, as the depth simply increases with the length.

Key Fitting. — The proper method of fitting keys depends somewhat upon the type of key used. The tapered sunk key not only acts as a driver for the keyed part, but holds it against axial or endwise movement, and should have a bearing on all sides. The straight sunk key should have a good bearing on the sides, and ordinarily there is either a slight clearance at the top or a light bearing. When a straight key is to resist endwise, as well as rotary, movement, it is made to bear all over, but, in any case, the principal bearing should be on the sides. The saddle key, which is simply concaved on one side to fit the shaft and is tapered on the top, should be so fitted that it bears lightly on the sides and heavily between the shaft and hub throughout its entire length. As the drive with this type of key is not positive, it is only used when there is little power to transmit. The flat key, which is of rectangular section and bears against a flat surface on the shaft, is fitted practically in the same manner as the saddle key. The corners of all keys should be filed off slightly before driving, to prevent a heavy bearing at these points. When fitting Woodruff keys, it is good practice to bevel the circular edges somewhat to insure the key entering easily.

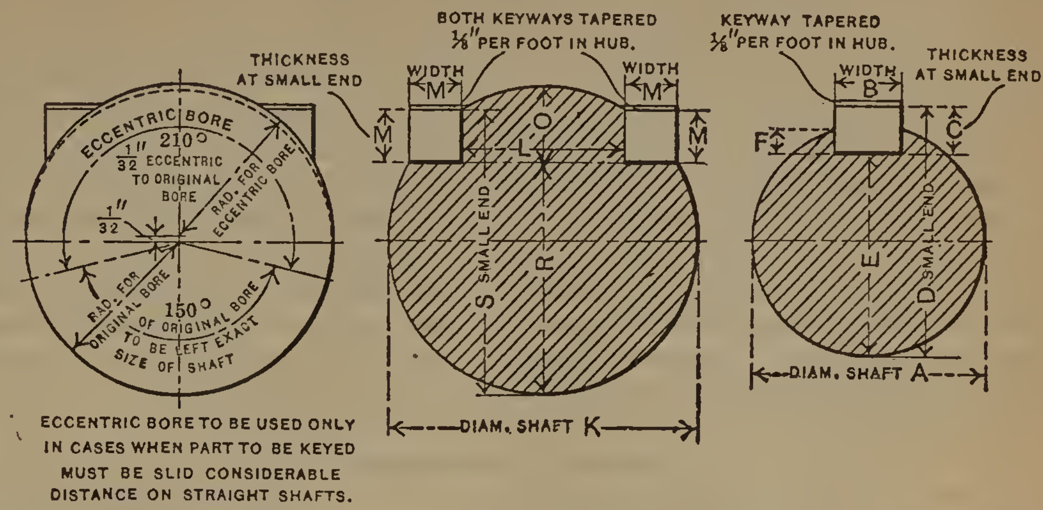
* For notation see illustration accompanying paragraph, "Gaging Depths of Keyseats."

Kennedy Double and Single Keys



For shafts above 6 inches in diameter, double keys should be used. If the torque is intermittent and power is transmitted alternately in opposite directions, double keys should be used for diameters down to and including 4 inches. Single keys may be used for sizes up to and including 6 inches, provided the torque is quite constant and the power transmission is always in one direction.

The sides and bottom of the keyway in a shaft should be straight and parallel. In the hub, the sides should be straight and parallel and the bottom tapered ⅛ inch per foot.

Double Keys

K	L	M	O	R	S	K	L	M	O	R	S

The Kennedy Key. — The Kennedy or double key system is used in rolling mills and is adapted to the transmission of heavy loads, especially where the torque is intermittent and the direction of rotation periodically reversed. Each key is so located that a diagonal line passing through two corners of the key approximately intersects the shaft axis. The keys have a taper of $\frac{1}{8}$ inch per foot on the hub side and the sides fit closely between the shaft and hub. The keys are driven in from opposite sides of the hub. When the part to be keyed must be moved some distance along a straight shaft before attaching it, the hub is first bored to the exact size of the shaft, and then one side is rebored eccentrically with the original bore, the eccentricity being 1/32 inch, as indicated by the diagram accompanying the table of Kennedy keys. The keys are located on the eccentric side, and when a load is applied, they are in compression instead of being subjected to a shearing stress, as with the ordinary key. These keys should be made of 0.50 carbon steel, and whenever possible heads should be provided for driving and withdrawing.

Standard Square Shafts

1 3/8	1 11/16	.....	.....	1 3/8	1 7/8	....	....

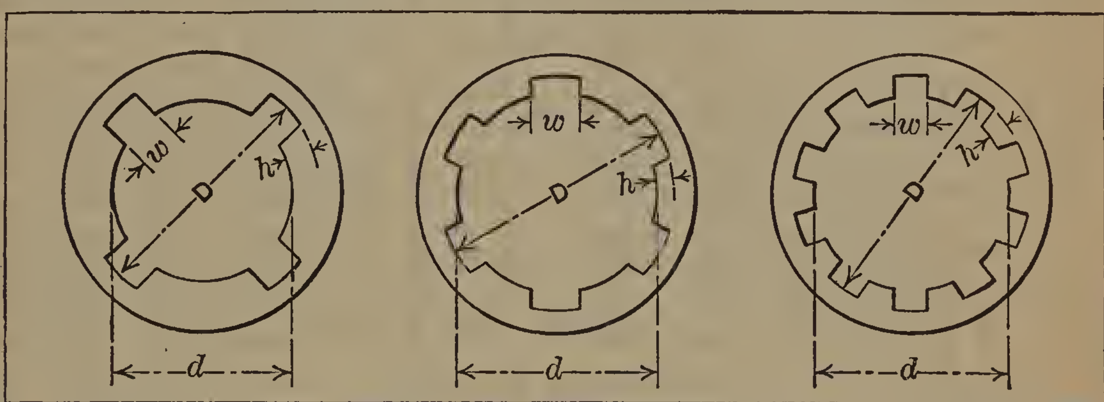
Square Shafts. — When square shafts are used in geared transmissions, etc., it is recommended that the holes be made to a standard size, for both sliding and fixed fits, and that the size of the shaft be varied to give the required fit. The relation between the diameter *B* (see engraving accompanying table, "Standard Square Shafts") across the corners and the width *A* of the square is in the ratio of 0.8 for fixed or permanent fits and also for non-loaded sliding fits, such as are employed for transmission gears; a ratio of 0.73 is used for fits that are required to slide while subjected to load. The table, "Proportions of Square Shafts and Fit Allowances," is based on the assumption that the parts containing the holes are not hardened; the shafts may be either soft or hardened.

Multiple Splines. — Multiple or "integral shaft" splines are used in automobile transmissions and the sliding-gear transmissions of machine tools, etc. The square shaft has been largely replaced by the multiple-spline shaft which is lighter for the same strength and provides a greater key-bearing area. The spline shafts may be produced quite rapidly by hobbing, the operation being the same, in principle, as hobbing spur gears; the grooves in the hubs or fittings which receive the shafts are broached. The S. A. E. standards for broached fittings include four-, six-, ten- and sixteen-spline fittings. The standard dimensions apply only to the soft broached hole and allowance must be made on the shaft to secure the required fit. The range of diameters of the different fittings will be given, with formulas for determining the sizes of the spline grooves.

Four-spline Fittings. — The maximum diameters D (see accompanying illustration) vary from 3/4 to 3 inches, inclusive, advancing by 1/8-inch increments up to 1 3/4 inch, and then by 1/4-inch increments up to 2 1/2 inches. For a permanent fitting, $d = 0.850\,D$; $h = 0.075\,D$; $w = 0.241\,D$. If the splined part is to slide when not under load, $d = 0.750\,D$; $h = 0.125\,D$; $w = 0.241\,D$. These formulas and those which follow for other classes of fittings give maximum dimensions. The minus tolerance for diameters D, d and for depth h is 0.001 inch for diameters up to and including 1 3/4 inch, and 0.002 for larger sizes. The tolerance for width w is 0.002 inch for diameters up to and including 1 3/4 inch, and 0.003 for larger sizes.

Six-spline Fittings. — The maximum diameters D vary from 3/4 to 3 inches inclusive, advancing by 1/8-inch increments up to 1 3/4 inch, and by 1/4-inch increments up to 2 1/2 inches. For a permanent fitting, $d = 0.900\,D$; $h = 0.050\,D$; $w = 0.250\,D$. For fittings that are to slide when not under load, $d = 0.850\,D$; $h = 0.075\,D$; $w = 0.250\,D$. If fittings are to slide when under load, $d = 0.800\,D$; $h = 0.100\,D$; $w = 0.250\,D$. All the tolerances are the same as previously given for four-spline fittings.

Ten-spline Fittings. — The maximum diameters D vary from 3/4 inch to 6 inches inclusive, advancing by 1/8-inch increments up to 1 3/4 inch; by 1/4-inch increments up to 2 1/2 inches and by 1/2-inch increments for larger sizes. For a permanent fit, $d = 0.910\,D$; $h = 0.045\,D$; $w = 0.156\,D$. For a fit to slide when not under load, $d = 0.860\,D$; $h = 0.070\,D$; $w = 0.156\,D$. For a fit to slide when under load, $d = 0.810\,D$; $h = 0.095\,D$; $w = 0.156\,D$. The tolerance for diameters D and d is 0.001 inch for sizes up to and including 1 3/4 inch, 0.002 inch for sizes up to and including 3 inches, and 0.003 inch for larger sizes. The tolerance for width w is 0.002 inch for diameters up to and including 1 3/4 inch and 0.003 inch for larger sizes.



Sixteen-spline Fittings. — The maximum diameters D vary from 2 to 6 inches inclusive, advancing by 1/2-inch increments. The formulas for dimensions d and h are the same as for ten-spline fittings. The width $w = 0.098\,D$ for a permanent fit and when the fitting is to slide either under load or not under load. The tolerance for dimensions D, d and w is 0.003 inch.

Torque Capacity of Spline Fittings. — The torque capacity of spline fittings, per inch of bearing length at 1000 pounds pressure per square inch on the sides of the spline, may be determined by the following formula, in which T = torque capacity in inch-pounds per inch of length, N = number of splines, R = mean radius or radial distance from center of hole to center of spline, h = depth of spline:

$$T = 1000\,NRh$$

Proportions of Square Shafts and Fit Allowances

CLUTCHES AND COUPLINGS

Positive Clutches. — When the driving and driven members of a clutch are connected by the engagement of interlocking teeth or projecting lugs, the clutch is said to be "positive" to distinguish it from the type in which the power is transmitted by frictional contact. The positive clutch is employed when a sudden starting action is not objectionable and when the inertia of the driven parts is relatively small. The various forms of positive clutches differ merely in the angle or shape of the engaging surfaces. The least positive form is one having planes of engagement which incline backward, with respect to the direction of motion. The tendency of such a clutch is to disengage under load, in which case it must be held in

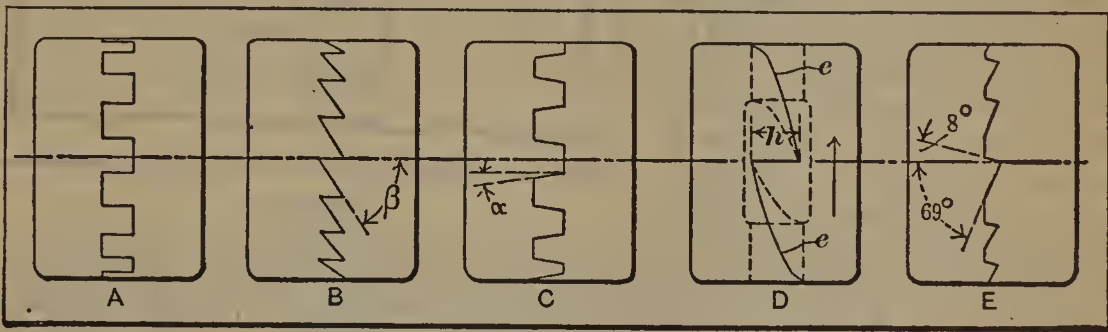

Fig. 1.— Types of Clutch Teeth

position by axial pressure. This pressure may be regulated to perform normal duty, permitting the clutch to slip and disengage when over-loaded. Positive clutches, with the engaging planes parallel to the axis of rotation, are held together to obviate the tendency to jar out of engagement, but they provide no safety feature against over-load. So-called "under-cut" clutches engage more tightly the heavier the load, and are designed to be disengaged only when free from load. The teeth of positive clutches are made in a variety of forms, a few of the more common styles being shown in Fig. 1. Clutch *A* is a straight-toothed type, and *B* has angular

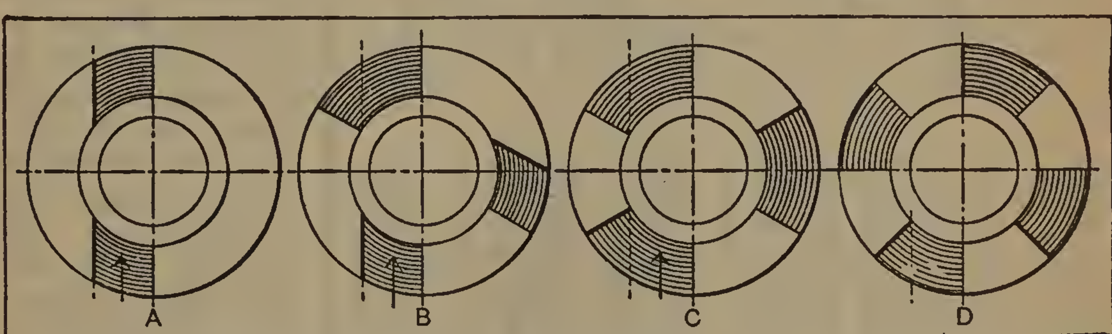

Fig. 2.— Diagrammatical View Showing Method of Cutting Clutch Teeth

or saw-shaped teeth. The driving member of the former can be rotated in either direction; the latter is adapted to the transmission of motion in one direction only, but is more readily engaged. The angle β of the cutter for a saw-tooth clutch *B* is ordinarily 60 degrees. Clutch *C* is similar to *A*, except that the sides of the teeth are inclined to facilitate engagement and disengagement. Teeth of this shape are sometimes used when a clutch is required to run in either direction without backlash. Angle α is varied to suit requirements and should not exceed 8 or 9 degrees. The straight-tooth clutch *A* is also modified to make the teeth engage more readily, by rounding the corners of the teeth at the top and bottom. Clutch *D* (commonly called a "spiral-jaw" clutch) differs from *B* in that the surfaces *e* are helicoidal. The driving member of this clutch can only transmit motion in one direction.

Clutches of this type are known as right- and left-hand, the former driving when turning to the right, as indicated by the arrow in the illustration. Clutch *E* is the form used on the back-shaft of the Brown & Sharpe automatic screw machines. The faces of the teeth are radial and incline at an angle of 8 degrees with the axis, so that the clutch can readily be disengaged. This type of clutch is easily operated, with little jar or noise. The 2-inch diameter size has 10 teeth. Height of working face, 1/8 inch.

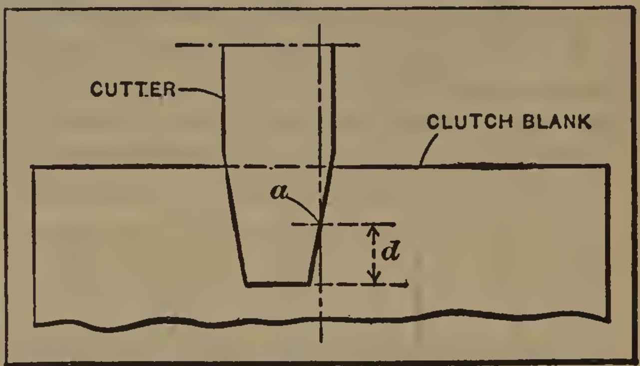

Fig. 3

Cutting Clutch Teeth. — A common method of cutting a straight-tooth clutch is indicated by the diagrams *A*, *B* and *C*, Fig. 2, which show the first, second and third cuts required for forming the three teeth. The work is held in the chuck of a dividing-head, the latter being set at right angles to the table. A plain milling cutter may be used (unless the corners of the teeth are rounded), the side of the cutter being set to exactly coincide with the center-line. When the number of teeth in the clutch is odd, the cut can be taken clear across the blank as shown, thus finishing the sides of two teeth with one passage of the cutter. When the number of teeth is even, as at *D*, it is necessary to mill all the teeth on one side and then set the cutter for finishing the opposite side. Therefore, clutches of this type commonly have an odd number of teeth. The maximum width of the cutter depends upon the width of the space at the narrow ends of the teeth If the cutter must be quite narrow in order to pass the narrow ends, some stock may be left in the tooth spaces, which must be removed by a separate cut. If the tooth is of the modified form shown at *C*, Fig. 1, the cutter should be set as indicated in Fig. 3; that is, so that a point *a* on the cutter at a radial distance *d* equal to one-half the depth of the clutch teeth lies in a radial plane. When it is important to eliminate all backlash, point *a* is sometimes located at a radial distance *d* equal to six-tenths of the depth of the tooth, in order to leave clearance spaces at the bottoms of the teeth; the two clutch members will then fit together tightly. Clutches of this type must be held in mesh.

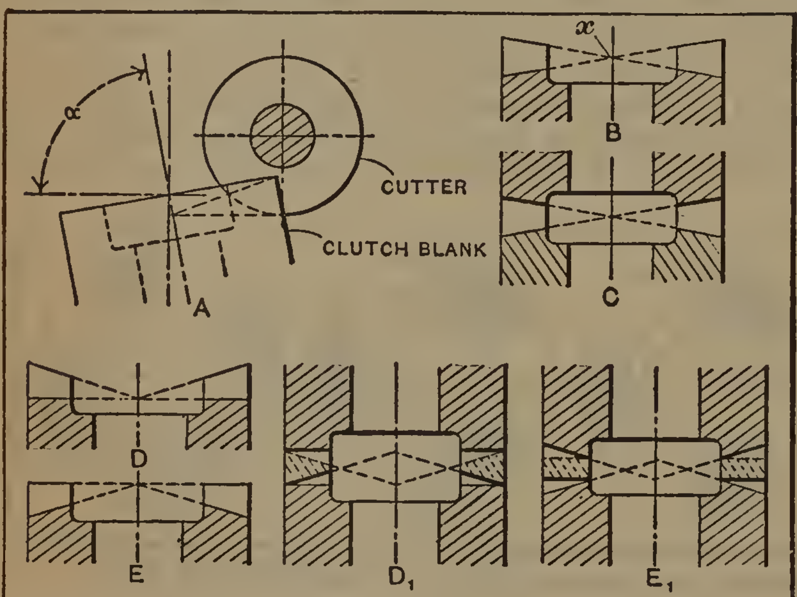

Fig. 4

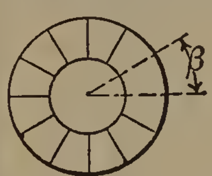
Cutting Saw-tooth Clutches. — When milling clutches having angular teeth as shown at *B*, Fig. 1, the axis of the clutch blank should be inclined a certain angle α from the vertical, as shown at *A* in Fig. 4. If the teeth were milled with the blank vertical, the tops of the teeth would incline towards the center as at D, whereas, if the blank were set to such an angle that the tops of the teeth were square with the axis, the bottoms would incline upwards as at E. In either case, the two clutch members would not mesh completely; the engagement of the teeth cut as shown at D and E would be as indicated at D_1 and E_1 respectively. As will be seen, when the outer points of the teeth at D_1 are at the bottom of the grooves in the opposite member, the inner ends are not together, the contact area being represented by the dotted lines. At E_1 the inner ends of the teeth strike first and spaces are left between the teeth around the outside of the clutch. To overcome this objectionable feature, the clutch teeth should be cut as indicated at B, or so that the bottoms and tops of the teeth have the same inclination, converging at a central point x. The teeth of both members will then engage across the entire width as shown at C. The angle α required for cutting a clutch as at B can be determined by the following formula in which α equals the required angle, and N, the number of teeth;

$$\cos \alpha = \tan \frac{180 \text{ deg.}}{N} \times \cot \text{ cutter angle.}$$

Expressing this formula as a rule: To determine the cosine of angle α (see diagram A, Fig. 4) find the tangent of the angle obtained by dividing 180 degrees by the number of teeth, and multiply this tangent by the cotangent of the cutter angle.

These angles for various numbers of teeth and for either a 60-, 70- or 80-degree cutter are given in the following table:

Angles for Setting Dividing-head when Cutting Clutches with Angular Cutters



The cosine of the angle to which the milling machine index head is set equals the sine of angle β (see illustration) multiplied by the cotangent of the cutter angle, divided by the cosine of angle β plus 1.

No. of Teeth	Angle of Cutter 60°	70°	80°	No. of Teeth	Angle of Cutter 60°	70°	80°

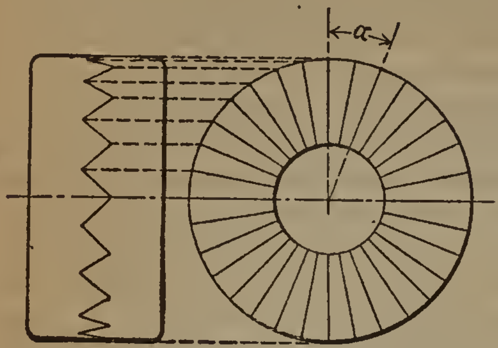
Friction Clutches. — Clutches which transmit motion from the driving to the driven member by the friction between the engaging surfaces are built in many different designs, although practically all of them can be classified under four general types, namely, conical clutches; radially-expanding clutches; contracting-

Angles for Setting Index Head when Milling V-shaped Grooves



The cosine of the angle to which to set the index head equals the tangent of one-quarter of angle α (α = 360 ÷ number of teeth) multiplied by the cotangent of one-half the cutter angle. Thus:

$$\cos \text{index-head angle} = \tan \frac{90}{N} \times \cot \frac{\text{cutter angle}}{2}$$

No. of Teeth	Included Angle of Cutter		No. of Teeth	Included Angle of Cutter	
	60°	90°		60°	90°

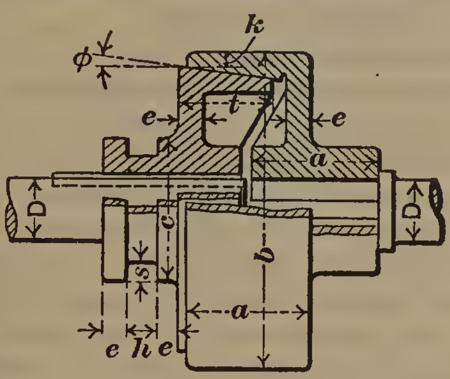
The angles given in the table above are applicable to the milling of V-shaped grooves in brackets, etc., which must have toothed surfaces to prevent the two members from turning relative to each other, except when unclamped for angular adjustment.

band clutches; and friction disk clutches in single and multiple types. There are many modifications of these general classes, some of which combine the features of different types. The proportions of various sizes of cone clutches are given in the table "Cast-iron Friction Clutches." The multi-cone friction clutch is a further development of the cone clutch. Instead of having a single cone-shaped surface, there is a series of concentric conical rings which engage annular grooves formed by corresponding rings on the opposite clutch member. The internal-expanding type is provided with shoes which are forced outward against an enclosing drum by the action of levers connecting with a collar free to slide along the shaft. The engaging shoes are commonly lined with wood to increase the coefficient of friction. The well-known Weston disk clutch is based on the principle of multiple-plane friction. It consists of a series of alternating plates or disks so arranged that one set engages with an outside cylindrical case and the other set with the shaft. When these plates are pressed together by spring pressure, or by other means, motion is transmitted from the driving to the driven members connected to the clutch. Some disk clutches have a few rather heavy or thick plates and others a relatively large number of thinner plates. Clutches of the latter type are common in automobile construction. One set of disks may be of soft steel and the other set of phosphor-bronze, or some other combination may be employed. For instance, disks are sometimes provided with cork inserts, or one set or series of disks may be faced with a special friction material such as asbestos-wire fabric, as in the case of "dry plate" clutches, the disks of which are not lubricated like the disks of a clutch having, for example, the steel and phosphor-bronze combination. It is common practice to hold the driving and driven members of friction clutches into engagement by means of spring pressure, although pneumatic and hydraulic pressure is sometimes employed.

Cast-iron Friction Clutches



For sizes not given below:

$a = 2\,D$
$b = 4$ to $8\,D$
$c = 2\frac{1}{4}\,D$
$t = 1\frac{1}{2}\,D$
$e = \frac{3}{8}\,D$
$h = \frac{1}{2}\,D$
$s = \frac{5}{16}\,D$, nearly
$k = \frac{1}{4}\,D$

Note:— The angle ϕ of the cone may be from 4 to 10 degrees.

Power Transmitting Capacity of Friction Clutches. — When selecting a clutch for a given class of service, it is advisable to consider any overloads that may be encountered and base the power transmitting capacity of the clutch upon such overloads. When the load varies or is subject to frequent release or engagement, the clutch capacity should be greater than the actual amount of power transmitted. If the power is derived from a gas or gasoline engine, the horsepower rating of the clutch should be 75 or 100 per cent greater than that of the engine.

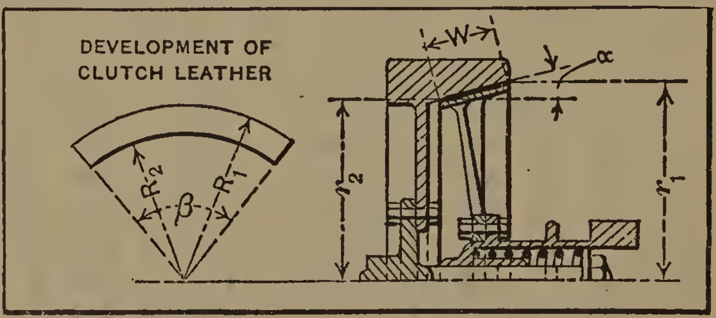
Formulas for Cone Clutches. — In cone clutch design, different formulas have been developed for determining the horsepower transmitted. These formulas, at first sight, do not seem to agree, there being a variation due to the fact that in some of the formulas the friction clutch surfaces are assumed to engage without slip, whereas, in others, some allowance is made for slip. The following formulas include both of these conditions:

H.P. = horsepower transmitted;
N = revolutions per minute;
r = mean radius of friction cone, in inches;
r_1 = large radius of friction cone, in inches;
r_2 = small radius of friction cone, in inches;
R_1 = outside radius of leather band, in inches;
R_2 = inside radius of leather band, in inches;
V = velocity of a point at distance r from the center, in feet per minute;
F = tangential force acting at radius r, in pounds;
P_n = total normal pressure between cone surfaces, in pounds;
P_s = spring pressure, in pounds;
α = angle of clutch surface with axis of shaft = 7 to 13 degrees;
β = included angle of clutch leather, when developed, in degrees;
f = coefficient of friction = 0.20 to 0.25 for greasy leather on iron;
p = allowable pressure per square inch of leather band = 7 to 8 pounds;
W = width of clutch leather, in inches.

$$R_1 = \frac{r_1}{\sin\alpha} \qquad R_2 = \frac{r_2}{\sin\alpha}$$

$$\beta = \sin\alpha \times 360 \qquad r = \frac{r_1 + r_2}{2}$$

$$V = \frac{2\pi r N}{12}$$



$$F = \frac{\text{H.P.} \times 33{,}000}{V} \qquad W = \frac{P_n}{2\pi r p} \qquad \text{H.P.} = \frac{P_n f r N}{63{,}025}$$

For engagement with some slip:

$$P_n = \frac{P_s}{\sin\alpha} \qquad P_s = \frac{\text{H.P.} \times 63{,}025 \sin\alpha}{frN}$$

For engagement without slip:

$$P_n = \frac{P_s}{\sin\alpha + f\cos\alpha} \qquad P_s = \frac{\text{H.P.} \times 63{,}025\,(\sin\alpha + f\cos\alpha)}{frN}$$

Angle of Cone. — If the angle of the conical surface of the cone type of clutch is too small, it may be difficult to release the clutch on account of the wedging effect, whereas, if the angle is too large, excessive spring pressure will be required to prevent slipping. The minimum angle for a leather-faced cone is about 8 or 9 degrees and the maximum angle about 13 degrees. An angle of 12½ degrees appears to be the most common and is generally considered good practice. These angles are given with relation to the clutch axis and are one-half the included angle.

Power Transmitted by Disk Clutches. — The approximate amount of power that a disk clutch will transmit may be determined from the following formula, in which H = horsepower transmitted by the clutch: μ = coefficient of friction; r = mean radius of engaging surfaces; F = axial force in pounds (spring pressure) holding disks in contact; N = number of frictional surfaces; S = speed of shaft in revolutions per minute:

$$H = \frac{\mu r F N S}{63{,}000}$$

Frictional Coefficients for Clutch Calculations. — While the frictional coefficients used by designers of clutches differ somewhat and depend upon variable factors, the following values may be used in clutch calculations: For greasy leather on cast iron about 0.20 or 0.25; leather on metal that is quite oily 0.15; metal and cork on oily metal 0.32; the same on dry metal 0.35; metal on dry metal 0.15; disk clutches having lubricated surfaces 0.10.

Magnetic Clutches. — Clutches of the magnetic type, like other electrical apparatus, are adapted to remote and automatic control. They are especially applicable for high-speed drives; for heavy duty; for use with motors that cannot start heavy loads; and for stopping machinery quickly, in which case a brake is used in combination with the clutch. The Cutler-Hammer magnetic clutch has a field or driving member and an armature or driven member. Each of these parts is carried by a flexible spring steel plate so that when current passes through the winding of the field, the armature is attracted to it and the friction surfaces come into engagement. The turning power of the clutch depends entirely upon the friction surfaces which are held together by magnetic attraction. Current is conducted to the magnetizing winding of the field through two collector rings and graphite brushes. These clutches are operated by direct current. The ratings of some of the different sizes are given in the accompanying table.

Magnetic Clutch Ratings *

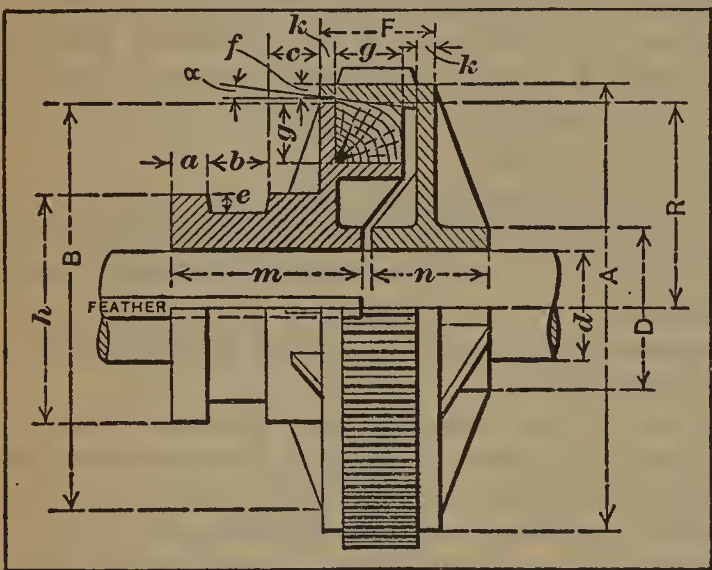
Friction Clutches for Hoisting Machinery. — In the operation of hoisting machinery, it is important that certain motions be engaged without stopping the motor. This is done by friction clutches in which one portion is keyed to the shaft while the other is keyed to the member to be driven. Arrangement is made to thrust the two portions of a clutch together and lock them in frictional engagement. The dimensions below give proportions for couplings for hoisting machinery.



$A = 4d$ to $8d$;
$f = 0.2d + 0.1$ inch;
$B = A - (2f + ¼$ inch);
$h = 2d + 1$ inch;
$c = 0.5d$;
$a = 0.3d + 0.3$ inch;
$b = 0.4d + 0.4$ inch;
$e = 0.3d + 0.1$ inch;
$k = 0.2d + 0.3$ inch;
$g = d$ to $1.4d$;
$D = 1.8d + 0.5$ inch;
$F = (1.4d$ to $1.8d)$ + 1 inch;
$m = 2d$;
$n = d$ to $1.5d$.

Authorities differ as to the angle α, making it all the way from 2 to 10 degrees. A good average angle for general purposes is 7 degrees.

Clutches with Cork Inserts. — The friction surfaces of some clutches have cork inserts, owing to the fact that cork has a high coefficient of friction — probably double that of wood or leather on iron. As a rule, the cork, which has previously been boiled and thereby softened, is forced into suitable cavities formed in one of the metallic friction surfaces. When so inserted, it normally protrudes above

the surrounding surface and engages first. If sufficient pressure is applied to the clutch, the cork is pressed down flush with the metal surface and acts with it in carrying the load. Two forms of cork are used, one being cork in its natural condition and the other prepared as follows: Small pieces are compressed into sheets and blocks of any desired shape, under great pressure and while subjected to enough heat to cause the natural gums of the cork to exude and act as a binder. This prepared cork is more enduring than the natural; it is stronger and firmer, and yet possesses considerable elasticity. It is expensive, however, and for that reason has not been widely used. The coefficient of friction with cork-insert surfaces averages about 0.34, whereas the average coefficient of friction for cast iron on cast iron is about 0.16, and for bronze on cast iron, about 0.14. It is claimed that the coefficient of friction of cork is not lessened very much by lubrication. Cork is also affected very little by moisture.

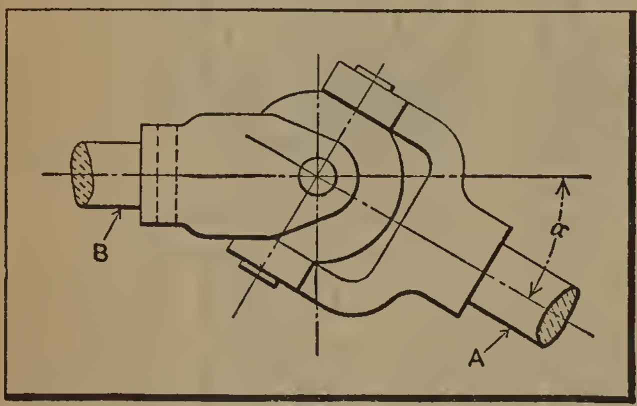
The Universal Joint. — This form of coupling, originally known as Hooke's coupling, is used for connecting two shafts the axes of which are not in line with each other, but which merely intersect at a point. There are many different designs of universal joints or couplings, which are based on the principle embodied in the original design. One well-known type is shown by the accompanying diagram. A fork- or U-shaped member is attached to each shaft and is pivoted to a connecting piece. The axes of the four bearings should lie in the same plane as shown by the diagram, although some universal joints are so made that two of the bearings are offset and not in the same plane as the other two. With this construction, which has only a very limited use, only one of the connected shafts can be held rigidly and permit rotary motion.

As a rule, a universal joint does not work well if the angle α (see illustration) is more than 45 degrees, and the angle should preferably be limited to about 20 degrees or 25 degrees, excepting when the speed of rotation is slow and little power is transmitted.

Variation in Angular Velocity of Driven Shaft. — Owing to the angularity between two shafts connected by a universal joint, there is a variation in the angular velocity of one shaft during a single revolution, and because of this, the use of universal couplings is sometimes prohibited. Thus, the angular velocity of the driven shaft will not be the same at all points of the revolution as the angular velocity of the driving shaft. In other words, if the driving shaft moves with a uniform motion, then the driven shaft will have a variable motion and, therefore, the universal joint should not be used when absolute uniformity of motion is essential for the driven shaft.

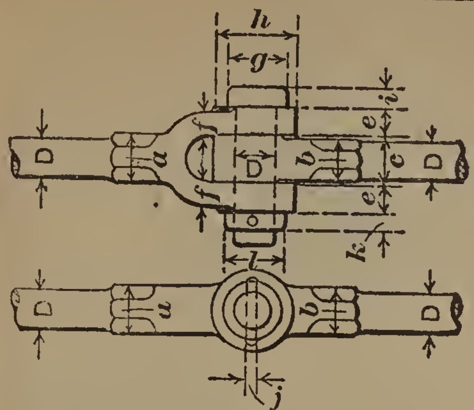
Determining Maximum and Minimum Velocities. — If shaft A (see diagram) runs at a constant speed, shaft B revolves at maximum speed when shaft A occupies the position shown in the illustration, and the minimum speed of shaft B occurs when the fork of the driving shaft A has turned 90 degrees from the position illustrated. The maximum speed of the driven shaft may be obtained by multiplying the speed of the driving shaft by the secant of angle α. The minimum speed of the driven shaft equals the speed of the driver multiplied by cosine α. Thus, if the driver rotates at a constant speed of 100 revolutions per minute and the shaft angle is 25 degrees, the maximum speed of the driven shaft is at a rate equal to $1.1034 \times 100 = 110.34$ R.P.M. The minimum speed rate equals $0.9063 \times 100 = 90.63$; hence, the extreme variation equals $110.34 - 90.63 = 19.71$ R.P.M.



Use of Intermediate Shaft between Two Universal Joints. — The lack of uniformity in the speed of the driven shaft resulting from the use of a universal coupling, as previously explained, is objectionable for some forms of mechanisms. This variation may be avoided if the two shafts are connected with an intermediate shaft and two universal joints, provided the latter are properly arranged or located. Two conditions are necessary to obtain a constant speed ratio between the driving and driven shafts. First, the shafts must make the same angle with the intermediate shaft; second, the universal joint forks (assuming that the fork design is employed) on the intermediate shaft must be placed relatively so that when the plane of the fork at the left end coincides with the center lines of the intermediate shaft and the shaft attached to the left-hand coupling, the plane of the right-hand fork must also coincide with the center lines of the intermediate shaft and the shaft attached to the right-hand coupling; therefore the driving and the driven shafts may be placed in a variety of positions. One of the most common arrangements, however, is with the driving and driven shafts parallel. In this case, the forks on the intermediate shafts should be placed in the same plane.

This intermediate connecting shaft is frequently made telescoping, and then the driving and driven shafts can be moved independently of each other within certain limits in longitudinal and lateral directions. The telescoping intermediate shaft consists of a rod which enters a sleeve and is provided with a suitable spline, to prevent rotation between the rod and sleeve and permit a sliding movement. This arrangement is applied to various machine tools.

Proportions of Knuckle Joints



For sizes not given below:

$a = 1.2\,D$	$h = 2\,D$
$b = 1.1\,D$	$i = 0.5\,D$
$c = 1.2\,D$	$j = 0.25\,D$
$e = 0.75\,D$	$k = 0.5\,D$
$f = 0.6\,D$	$l = 1.5\,D$
$g = 1.5\,D$

Flexible Couplings. — Flexible couplings are used mostly for coupling together electrical machinery or for coupling electrical to other machinery. The general types of flexible couplings include the leather link coupling, the endless belt coupling, and the rubber buffer coupling. The leather link coupling consists of two iron castings with flanges which are connected by leather links and bolts. The bolts are generally six in number and each alternate bolt is tightly fitted in the flange of one casting, but has considerable play in the other. The leather links are placed around pairs of adjacent bolts and provide a slight flexibility for the drive. This coupling is adapted for shafts up to 3½ inches in diameter. The endless belt flexible coupling is adapted for shafts of larger diameter. It consists of two steel rings, one outer and one inner, in which slots are formed and through which two endless leather belts are interwoven. The rubber buffer coupling is formed of two disks; the driving side transmits motion to the driven side by means of studs, bolts or interlocking arms surrounded by heavy rubber bushings which give the necessary flexibility. The "mill type" flexible coupling, which is used chiefly in steel mills, is formed of three steel castings and is adapted to severe service.

FRICTION BRAKES

Formulas for Band Brakes. — In any band brake, such as shown in Fig. 1, in the tabulation of the formulas, where the brake wheel rotates in a clockwise direction, the tension in that part of the band marked x equals $P\,\dfrac{1}{e^{\mu\theta} - 1}$

The tension in that part marked y equals $P\,\dfrac{e^{\mu\theta}}{e^{\mu\theta} - 1}$

P = tangential force in pounds at rim of brake wheel;
e = base of natural logarithms = 2.71828;
μ = coefficient of friction between the brake band and the brake wheel;
θ = angle of contact of the brake band with the brake wheel expressed in radians (one radian $= \dfrac{180 \text{ deg.}}{\pi} = 57.296$ degrees).

For simplicity in the formulas presented, the tensions at x and y (Fig. 1) are denoted by T_1 and T_2 respectively, for clockwise rotation. When the direction of the rotation is reversed, the tension in x equals T_2, and the tension in y equals T_1, which is the reverse of the tension in the clockwise direction.

The value of the expression $e^{\mu\theta}$ in these formulas may be most easily solved by means of logarithms. The value of $e^{\mu\theta}$ is found by multiplying the logarithm of e by the product of the numerical values of μ and θ, and finding the number whose logarithm is equal to the result of this multiplication. The procedure may be best illustrated by an example.

Formulas for Simple and Differential Band Brakes

F = force in pounds at end of brake handle; P = tangential force in pounds at rim of brake wheel; e = base of natural logarithms = 2.71828; μ = coefficient of friction between the brake band and the brake wheel; θ = angle of contact of the brake band with the brake wheel, expressed in radians (one radian = $\frac{180°}{\pi}$ = 57.296 degrees).

$$T_1 = P\frac{1}{e^{\mu\theta}-1} \qquad T_2 = P\frac{e^{\mu\theta}}{e^{\mu\theta}-1}$$

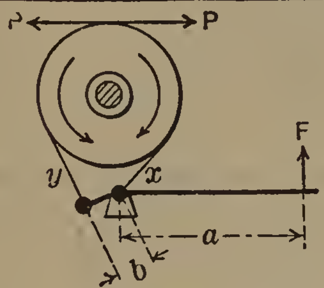

Fig. 1

Simple band brake.
For clockwise rotation:

$$F = \frac{bT_2}{a} = \frac{Pb}{a}\left(\frac{e^{\mu\theta}}{e^{\mu\theta}-1}\right)$$

For counter clockwise rotation:

$$F = \frac{bT_1}{a} = \frac{Pb}{a}\left(\frac{1}{e^{\mu\theta}-1}\right)$$

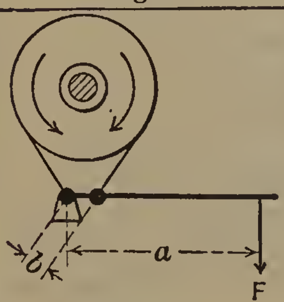

Fig. 2

Simple band brake.
For clockwise rotation:

$$F = \frac{bT_1}{a} = \frac{Pb}{a}\left(\frac{1}{e^{\mu\theta}-1}\right)$$

For counter clockwise rotation:

$$F = \frac{bT_2}{a} = \frac{Pb}{a}\left(\frac{e^{\mu\theta}}{e^{\mu\theta}-1}\right)$$

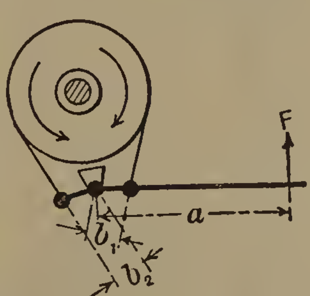

Fig. 3

Differential band brake.
For clockwise rotation:

$$F = \frac{b_2T_2 - b_1T_1}{a} = \frac{P}{a}\left(\frac{b_2e^{\mu\theta}-b_1}{e^{\mu\theta}-1}\right)$$

For counter clockwise rotation:

$$F = \frac{b_2T_1 - b_1T_2}{a} = \frac{P}{a}\left(\frac{b_2-b_1e^{\mu\theta}}{e^{\mu\theta}-1}\right)$$

In this case, if b_2 is equal to, or less than, $b_1e^{\mu\theta}$, the force F will be 0 or negative and the band brake works automatically.

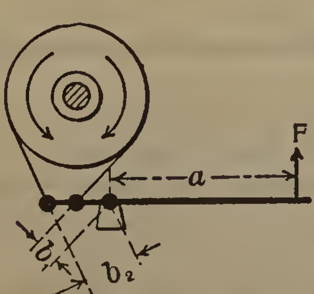

Fig. 4

Differential band brake.
For clockwise rotation:

$$F = \frac{b_2T_2 + b_1T_1}{a} = \frac{P}{a}\left(\frac{b_2e^{\mu\theta}+b_1}{e^{\mu\theta}-1}\right)$$

For counter clockwise rotation:

$$F = \frac{b_1T_2 + b_2T_1}{a} = \frac{P}{a}\left(\frac{b_1e^{\mu\theta}+b_2}{e^{\mu\theta}-1}\right)$$

If $b_2 = b_1$, both of the above formulas reduce to $F = \frac{Pb_1}{a}\left(\frac{e^{\mu\theta}+1}{e^{\mu\theta}-1}\right)$. In this case, the same force F is required for rotation in either direction.

In a band brake of the type in Fig. 1, dimension $a = 24$ inches, and $b = 4$ inches; force $P = 100$ pounds; coefficient $\mu = 0.2$, and angle of contact = 240 degrees, or

$$\theta = \frac{240}{180} \times \pi = 4.18.$$

The rotation is clockwise. Find force F required.

$$F = \frac{Pb}{a}\left(\frac{e^{\mu\theta}}{e^{\mu\theta} - 1}\right) = \frac{100 \times 4}{24}\left(\frac{2.71828^{0.2\times 4.18}}{2.71828^{0.2\times 4.18} - 1}\right)$$

$$= \frac{400}{24} \times \frac{2.71828^{0.836}}{2.71828^{0.836} - 1} = 16.66 \times \frac{2.31}{2.31 - 1} = 29.4.$$

The calculations for determining the value of $e^{\mu\theta}$ are rather cumbersome, and the accompanying table will save calculations.

Table of Values of $e^{\mu\theta}$

Proportion of Contact to Whole Circumference, $\frac{\theta}{2\pi}$	Steel Band on Cast Iron, $\mu = 0.18$	Leather Belt on			
		Wood	Cast Iron		
		Slightly Greasy; $\mu = 0.47$	Very Greasy; $\mu = 0.12$	Slightly Greasy; $\mu = 0.28$	Damp; $\mu = 0.38$

1.0	3.10	19.20	2.12	5.81	10.90

Coefficient of Friction in Brakes. — The coefficients of friction that may be assumed for friction brake calculations are as follows: Iron on iron, 0.25 to 0.3; leather on iron, 0.3; cork on iron, 0.35. Values somewhat lower than these should be assumed when the velocities exceed 400 feet per minute at the beginning of the braking operation.

For brakes where wooden brake blocks are used on iron drums, poplar has proved the best brake-block material. The best material for the brake drum is wrought iron. Poplar gives a high coefficient of friction, and is little affected by oil. The average coefficient of friction for poplar brake blocks and wrought-iron drums is

0.6; for poplar on cast iron, 0.35; for oak on wrought iron, 0.5; for oak on cast iron, 0.3; for beech on wrought iron, 0.5; for beech on cast iron, 0.3; for elm on wrought iron, 0.6; and for elm on cast iron, 0.35. The objection to elm is that the friction decreases rapidly if the friction surfaces are oily. The coefficient of friction for elm and wrought iron, if oily, is less than 0.4.

Formulas for Block Brakes

F = force in pounds at end of brake handle;
P = tangential force in pounds at rim of brake wheel;
μ = coefficient of friction between the brake block and brake wheel.

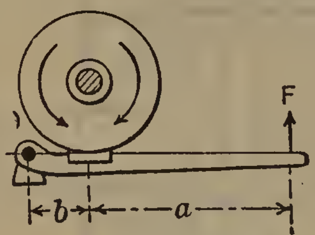

Fig. 1

Block brake.
For rotation in either direction:

$$F = P\frac{b}{a+b} \times \frac{1}{\mu} = \frac{Pb}{a+b}\left(\frac{1}{\mu}\right)$$

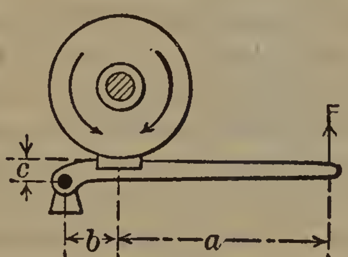

Fig. 2

Block brake.
For clockwise rotation:

$$F = \frac{\frac{Pb}{\mu} - Pc}{a+b} = \frac{Pb}{a+b}\left(\frac{1}{\mu} - \frac{c}{b}\right)$$

For counter clockwise rotation:

$$F = \frac{\frac{Pb}{\mu} + Pc}{a+b} = \frac{Pb}{a+b}\left(\frac{1}{\mu} + \frac{c}{b}\right)$$

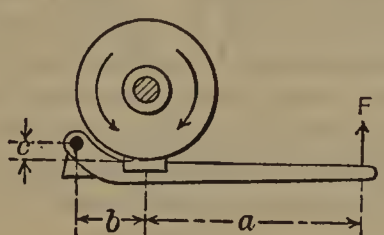

Fig. 3

Block brake.
For clockwise rotation:

$$F = \frac{\frac{Pb}{\mu} + Pc}{a+b} = \frac{Pb}{a+b}\left(\frac{1}{\mu} + \frac{c}{b}\right)$$

For counter clockwise rotation:

$$F = \frac{\frac{Pb}{\mu} - Pc}{a+b} = \frac{Pb}{a+b}\left(\frac{1}{\mu} - \frac{c}{b}\right)$$

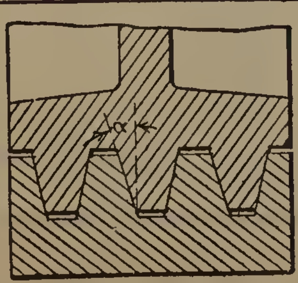

Fig. 4

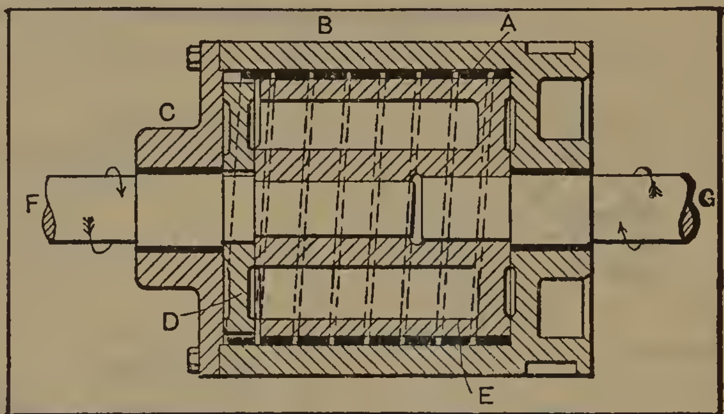
The brake wheel and friction block of the block brake are often grooved as shown in Fig. 4. In this case, substitute for μ in the above equations the value $\frac{\mu}{\sin\alpha + \mu\cos\alpha}$ where α is one-half the angle included by the faces of the grooves.

Coil Brakes. — The coil brake, as shown in the accompanying illustration, is used as an automatic brake. It is, in effect, an internal band brake. The ratio between the tensions at the ends of the strap equals k, the value of k being obtained by the formula:

$$\text{hyp. log } k = \mu \times \frac{l}{r}$$

in which μ = coefficient of friction; l = length of the circular arc in contact with the strap; and r = radius of drum. The accompanying table gives the value of k figured for a coefficient of friction equal to 0.33 for various arcs of contact.



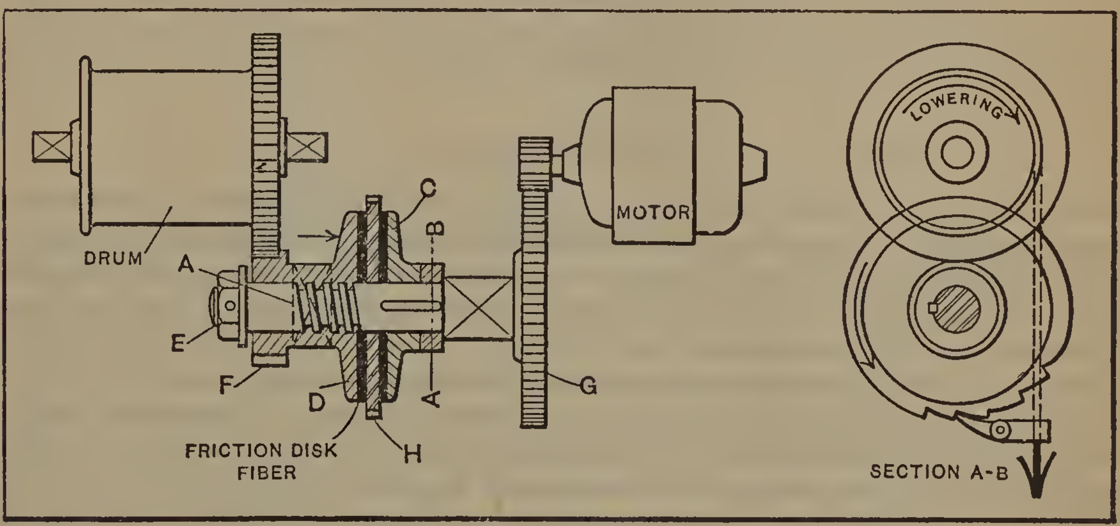
In the illustration, drum E is mounted on the ends of the motor shaft F and pinion shaft G, the former being loose and the latter keyed to the drum. Coil A is made of flat rod wound into a helix and ground on the external and internal surfaces, the diameter of the former being made slightly greater than the internal diameter of casing B, so that the coil must be slightly compressed when assembling the brake. One end of the coil is fastened to flange D, keyed to shaft F, and the other end is fastened to drum E. The coils may be made of steel or bronze bars. When properly designed with ample friction surfaces, and many coils with sufficient heat radiating surface, it is one of the most satisfactory types of brakes and seems especially adapted to the electric crane. In hoisting a load, shaft F turns in the direction of the arrow at the left, thus expanding the coil against the casing and causing drum E and shaft G to revolve with the casing. When holding a load suspended, shaft G and drum E tend to turn in the direction of the arrow at the right under the action of the load, thus expanding the coil against the casing, which is prevented from turning by pawls engaging the ratchet teeth on the end of the casing. When lowering the load, the motor turns in a direction opposite to that of the arrow at the left, thus releasing coil after coil from contact with the casing and winding them on drum E. When sufficient coils have been thus released, shaft G will turn under the influence of the load in the direction of the right-hand arrow, thus again expanding the coil sufficiently to hold the load. This cycle of events is repeated an infinite number of times in a unit of time, thus causing a uniform descent of the load.

Table of Values of k for Different Arcs of Contact

Arc of Contact, Degrees	Number of Revolutions	k	Arc of Contact, Degrees	Number of Revolutions	k
360	1	8.1	2880	8	18,913,800
720	2	65.9	3600	10	1,247,380,000
1440	4	4350.0	....	......	....

Formulas for Calculating Friction Disk Brakes. — In the following are given a set of formulas for calculations relating to the friction disk brake generally used on electric hoists. The object of the brake is to permit the lowering of the load at a constant speed with the power reversed, and the holding of the load suspended when the current in the motor is shut off. When the load is lowered it rotates, by means of the drum and gearing, the flange D against the ratchet disk H; the flange D is mounted as a nut on screw A; flange C is keyed to the shaft. The pawl engaging with the ratchet disk does not permit it to rotate when the load is lowered. As the ratchet disk thus is stationary, the work of the motor and of the lowered load must equal the work absorbed by the friction surfaces in the brake. When hoisting, the motor rotates flange D against flange C, thereby gripping friction plates and the ratchet H; the motor is thus free to hoist the load without any frictional resistance.

The amount of opening between the friction disks should be as small as possible, and the number of teeth in the ratchet disk as great as possible, consistent with the required strength. In this way excessive pressure on the ratchet teeth, due to the sudden dropping of the load when the current in the motor is shut off after



hoisting, may be avoided. The drop of the load is proportional to the opening between the friction disks and the amount the pawl allows the ratchet disk to rotate before engaging a tooth and stopping it positively.

In the formulas:

E = energy absorbed by friction disks in foot-pounds per minute;
E_1 = energy of the lowered load in foot-pounds;
E_2 = energy of the motor in foot-pounds;
e_1 = total efficiency of mechanism between load and flange D;
e_2 = total efficiency of the mechanism between the motor and flange C;
T = torque in inch-pounds on pinion F;
r = mean radius of screw in inches;
r_1 = inside radius of friction disks in inches;
r_2 = outside radius of friction disks in inches;
n = number of friction surfaces;
N = number of revolutions per minute of flanges C and D;
A = area of each friction disk in square inches;
W = total pressure in pounds on friction disk;
f = coefficient of friction between the flanges and the friction disks;
P = lead of the screw in inches;
ϕ = angle of repose of screw in degrees;
α = helix angle of the thread of screw in degrees;

y = number of thermal units of heat conducted away per square inch of bearing surface per minute; y may be considered to be from 4 to 7, when the mechanism is exposed to a current of cold air and in intermittent service, and as equal to 0.75 to 1 in tolerably cool places with intermittent service.

When a sufficient number of quantities are known, the energy absorbed by friction, the pressure on the disks, and the lead P of the screw in the brake may be found by the following formulas:

$$E = E_1e_1 + E_2e_2 \tag{1}$$

$$E = 0.349\,nfWN\,\frac{r_2^3 - r_1^3}{r_2^2 - r_1^2} \tag{2}$$

$$W = \frac{T}{r\tan(\alpha + \phi)} \tag{3}$$

$$P = 2\pi r\tan\alpha \tag{4}$$

$$y = \frac{E}{778 \times 2A} \tag{5}$$

Example: — Assume the following data: At 230 volts and a speed of 1000 revolutions per minute, 25 amperes are required for hoisting the load. At a speed of 1500 revolutions per minute, 9 amperes are required for lowering the load. The motor efficiency is 80 per cent, the drum is 12 inches in diameter, the drum gear ratio is 1 to 7, and the motor gear ratio is 6 to 1. The efficiency of each set of gearing is 90 per cent. The outside radius of the friction disks is 7 inches, the inside radius, 3 inches, and the mean radius of the screw, $1\frac{1}{4}$ inch. The number of friction disks is 2, the number of revolutions of the friction disks is $1500 \div 6 = 250$, the coefficient of friction between the flanges and the friction disks is 0.07, and the angle of repose of the screw, 8 degrees 30 minutes. From these data it will be found that the maximum load of 2200 pounds may be hoisted at a speed of 75 feet per minute and lowered at a speed of 112.5 feet per minute:

$$\frac{1000 \times 12 \times 3.14}{6 \times 7 \times 12} = 75 \text{ (hoisting speed);}$$

$$75 \times 1.5 = 112.5 \text{ (lowering speed);}$$

$$\frac{230 \times 25 \times 44.2 \times 80 \times 90 \times 90}{75 \times 100 \times 100 \times 100} = 2200 \text{ pounds, nearly (max. load).}$$

Now find the lead P of a screw which will give a lowering speed of 112.5 feet per minute with the given conditions.

$$E_1e_1 = 2200 \times 0.90 \times 112.5 = 222{,}750 \text{ foot-pounds.}$$

$$E_2e_2 = 230 \times 9 \times 44.2 \times 0.90 \times 0.80 = 65{,}900 \text{ foot-pounds.}$$

From Formula (1):

$$E = E_1e_1 + E_2e_2 = 222{,}750 + 65{,}900 = 288{,}650 \text{ foot-pounds.}$$

From Formula (2):

$$W = \frac{E}{0.349\,nfN\,\dfrac{r_2^3 - r_1^3}{r_2^2 - r_1^2}} = \frac{288{,}650}{0.349 \times 2 \times 0.07 \times 250 \times 7.9} = 3000, \text{ approx.}$$

From Formula (3):

$$\tan(\alpha+\phi) = \frac{T}{Wr} = \frac{[(2200 \times 6) \div 7] \times 0.90}{3000 \times 1.25} = 0.453.$$

Hence, $\alpha+\phi = 24° \, 20'$, and $\alpha = 24° \, 20' - 8° \, 30' = 15° \, 50'$.

From Formula (4):

$$P = 2 \times 3.14 \times 1.25 \times \tan 15° \, 50' = 2.23 \text{ inches.}$$

This gives a screw of practically 2¼-inch lead. If a double thread is used the pitch will be 1⅛ inch.

From Formula (5):

$$y = \frac{288{,}650}{778 \times 2 \times 125.6} = 1.48,$$

which would be satisfactory when the brake is well exposed to the air.

The maximum allowable pressure per square inch on the friction disks should be limited to 200 pounds. In the example, the pressure equals:

$$\frac{W}{A} = \frac{3000}{125.6} = 24 \text{ pounds per square inch, approximately.}$$

Heat Radiation in Brakes. — The friction in brakes must be distributed over a sufficiently large area to prevent undue heating of the parts in contact. Brakes with wooden friction blocks on iron drums give satisfactory service if one square inch of friction surface is allowed for each 200 or 250 foot-pounds of energy absorbed per minute. Car brakes running with iron on iron, under conditions favorable to cooling, often absorb as much as 10,000 to 15,000 foot-pounds of energy per square inch of friction surface. Figures for other types of brakes will lie between these extremes. To facilitate radiation of heat, a ribbed exterior of the casing may be used for block brakes, and also thin ribs or vanes on the brake drum. All radiating surfaces should be left rough and black, because a finished or polished surface confines the heat instead of radiating it into the atmosphere.

Friction Wheels for Power Transmission

When a rotating member is driven intermittently and the rate of driving does not need to be positive, friction wheels are frequently used, especially when the amount of power to be transmitted is comparatively small. The driven wheels in a pair of friction disks should always be made of a harder material than the driving wheels, so that if the driven wheel should be held stationary by the load, while the driving wheel revolves under its own pressure, a flat spot may not be rapidly worn on the driven wheel. The driven wheels, therefore, are usually made of iron, while the driving wheels are made of or covered with, rubber, paper, leather, wood or fiber. The safe working pressures per inch of contact for various materials are as follows: Straw fiber, 150; leather fiber, 240; tarred fiber, 240; leather, 150; wood, 100 to 150; paper, 150.

The working values in the table for coefficients of friction for different combinations may be used. A smaller coefficient of friction should be employed when the linear velocity of the driver is very great, or when the driver is starting the driven wheel under load.

Horsepower of Friction Wheels. — Let D = diameter of friction wheel in inches; N = number of revolutions per minute; W = width of face in inches; f =

Working Values of Coefficient of Friction

Materials	Coefficient of Friction	Materials	Coefficient of Friction
Straw fiber and cast iron......	0.26	Tarred fiber and aluminum...	0.18
Straw fiber and aluminum....	0.27	Leather and cast iron.........	0.14
Leather fiber and cast iron....	0.31	Leather and aluminum........	0.22
Leather fiber and aluminum...	0.30	Leather and typemetal........	0.25
Tarred fiber and cast iron.....	0.15	Wood and metal...............	0.25
Paper and cast iron	0.20		

coefficient of friction; P = pressure in pounds, per inch width of face. Then:

$$\text{H.P.} = \frac{3.1416 \times D \times N \times P \times W \times f}{33{,}000 \times 12}$$

Assume

$$\frac{3.1416 \times P \times f}{33{,}000 \times 12} = C;$$

then,

$$\text{for } P = 100 \text{ and } f = 0.20, \quad C = 0.00016;$$
$$\text{for } P = 150 \text{ and } f = 0.20, \quad C = 0.00024;$$
$$\text{for } P = 200 \text{ and } f = 0.20, \quad C = 0.00032.$$

The horsepower transmitted is then:

$$\text{H.P.} = D \times N \times W \times C.$$

Example: — Find the horsepower transmitted by a pair of friction wheels; the diameter of the driving wheel is 10 inches, and it revolves at 200 revolutions per minute. The width of the wheel is 2 inches. The pressure per inch width of face is 150 pounds, and the coefficient of friction 0.20.

$$\text{H.P.} = 10 \times 200 \times 2 \times 0.00024 = 0.96 \text{ horsepower.}$$

Horsepower Which May be Transmitted by Means of a Clean Paper Friction Wheel of One-inch Face when Run Under a Pressure of 150 Pounds

(Rockwood Mfg. Co.)

It is necessary that friction wheels be kept clean, and if foreign substances are likely to enter between the friction surfaces they should be protected by suitable guards Rigid supports should be provided for shafts as close to the wheels as possible so that a proper driving contact is provided across the full face of the wheel. The wider the face, the more vital is this point, and the more difficult is it to accomplish. Hence, the faces of friction wheels should be kept as narrow as the design in general will permit.

Dynamometers

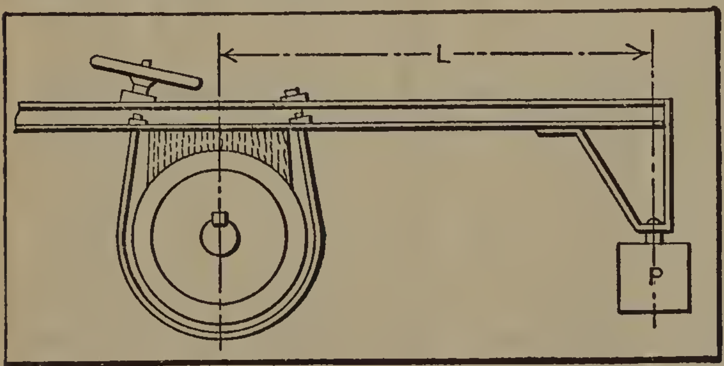
Dynamometers. — Dynamometers are instruments used for measuring power. One of the most common types is the Prony brake, which consists primarily of a lever connected to jaws which grip a revolving shaft or pulley so that the friction between the surfaces in contact tends to rotate the arm in the direction in which the shaft revolves. The tendency to rotation is overcome by weights supported at the end of the lever. The power for a given number of revolutions is measured by the weights required to balance the lever in a horizontal direction when the clamps are screwed up against the shaft so as to induce enough friction to raise the lever. The rubbing surfaces between the wooden blocks and the brake pulley are lubricated with heavy grease. Soft woods such as beech, poplar or maple should be used for brake blocks in preference to the harder woods.

Calculating Horsepower from Dynamometer Tests. — When a dynamometer is arranged for obtaining the horsepower transmitted by a shaft, as indicated by the diagrammatic view in the accompanying illustration, the horsepower may be obtained by the formula:

$$\text{H.P.} = \frac{2\pi LPN}{33{,}000}$$

in which H.P. = horsepower transmitted; N = number of revolutions per minute; L = distance (as shown in illustration) from center of pulley to point of action of weight P, in feet; P = weight hung on brake arm or read on scale.

By adopting a length of brake arm equal to 5 feet 3 inches, the formula may be reduced to the simple form:



$$\text{H.P.} = \frac{NP}{1000}$$

If a length of brake arm equal to 2 feet 7½ inches is adopted as a standard, the formula takes the form:

$$\text{H.P.} = \frac{NP}{2000}$$

The accompanying tables are based upon these formulas. They give the brake horsepower for velocities varying from 120 to 800 revolutions per minute. For example, assume that we wish to find the horsepower in a case where the shaft makes 300 revolutions per minute, a 60-pound weight being attached to a lever arm 5 feet 3 inches. Then, according to the simplified formula:

$$\text{H.P.} = \frac{NP}{1000} = \frac{300 \times 60}{1000} = 18$$

This value may be found directly from the tables by locating P = 60 in the extreme left-hand column, and N = 300 at the top of the columns. At the place where the two rows of figures intersect, the horsepower — in this case 18 — may be read off.

CAMS AND CAM DESIGN

Classes of Cams. — Cams may, in general, be divided into two classes: uniform motion cams and uniformly accelerated motion cams. The uniform motion cam moves the follower at the same rate of speed from the beginning to the end of the stroke; but as the movement is started from zero to the full speed of the uniform motion and stops in the same abrupt way, there is a distinct shock at the beginning and end of the stroke, if the movement is at all rapid. In machinery working at a high rate of speed, therefore, it is important that cams are so constructed that sudden shocks are avoided when starting the motion or when reversing the direction of motion of the follower. The cam best suited for high speeds is one where the speed at first is slow and then accelerated at a uniform rate until the maximum speed is reached. The speed is then again uniformly retarded until the rate of motion of the follower is zero or nearly zero when the reversal takes place. A cam constructed along these lines is called a uniformly accelerated motion cam. The distances

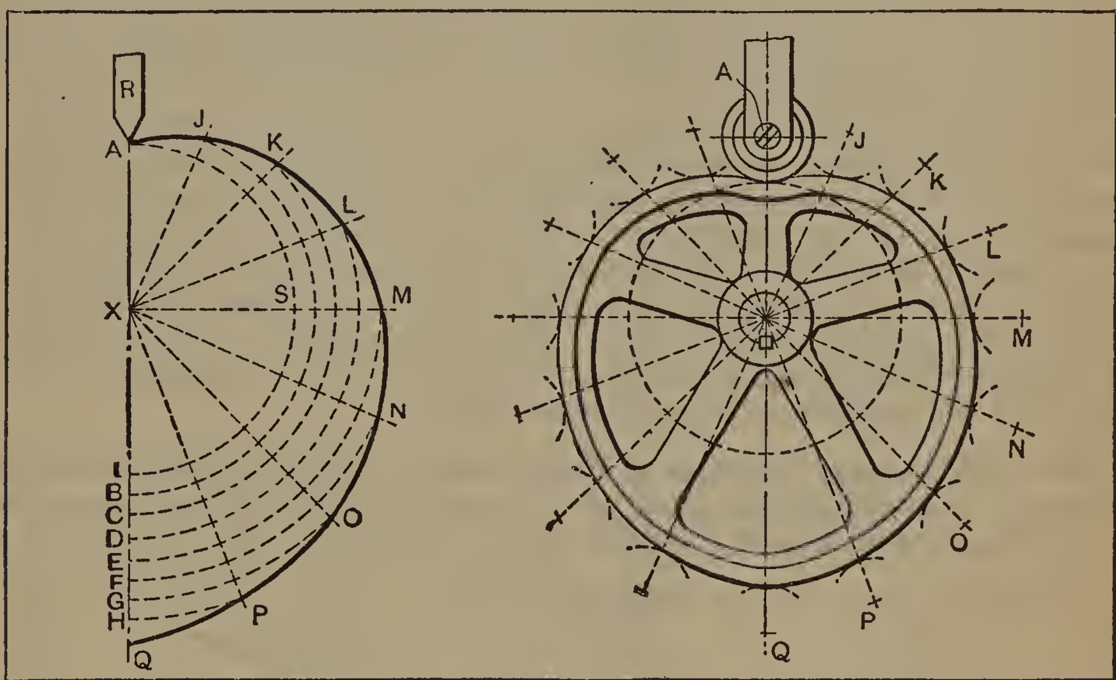

Fig. 1 Fig. 2

which the follower passes through during equal periods of time increase in the same ratio as the distances passed through in consecutive seconds by a freely falling body acted upon by gravity alone. A cam constructed on these lines, therefore, is often called a gravity-curve cam.

Laying-out a Uniform Motion Cam. — The laying-out of a heart-shaped cam will serve as an illustration of the general method. In Fig. 1, the pointed follower *R* is to be given a reciprocating motion. The throw is assumed to be 1½ inch. Let *X* be the center of the cam. Let *A* be the point at which the follower is at the lower end of the stroke. Draw semi-circle *ASI*, and extend the diameter at the side opposite *A*, a distance *IQ*, equal to the required throw. Divide *IQ* into any number of equal parts, as at *B*, *C*, *D*, etc., and divide the semi-circle by the same number of radii, equally distributed. With *X* as a center and a radius equal to *XB*, describe an arc intersecting *XJ* at *J*. With the same center and a radius equal to *XC*, describe an arc intersecting *XK* at *K*. Continue this process through the points *D*, *E*, *F*, etc., thus obtaining the points *L*, *M*, *N*, etc. The latter are points on the required curve. The other half of the cam is laid out in the same manner.

The excessive friction of a pointed follower such as that shown at *R* necessitates the use of a follower that will reduce the amount of friction to a minimum. A small roller meets this requirement. If a roller is employed as a follower, the problem of laying out the cam curve becomes modified. A roller traveling along the curve shown in Fig. 1 would not impart to the follower-rod the desired uniform rise and fall. The variation would be but slight, yet sufficient to merit consideration where accuracy is desired.

Cams with Roller Followers. — Fig. 2 represents a heart-shaped cam of the same dimensions as that in Fig. 1, but with a roller follower. It is the path of the center of this roller that requires consideration, as the position of this center regulates the throw. Therefore, the position of the center of the roller at various intervals in the rotation of the cam must be determined. This may be done by adding to each of the distances *XJ*, *XK*, etc., in Fig. 1, the radius of the roller, and thus obtaining the points *J*, *K*, *L*, etc., Fig. 2. With these points as centers and with radii equal to that of the roller, describe arcs. A curve drawn tangent to these arcs is the required cam curve.

This cam depends upon the action of gravity, or a spring, to keep the follower in contact with the driver. It can be made positive in action by the use of two followers placed at the extremities of the diameter of the cam, or by drawing curves tangent to both the top and bottom of the follower roller in its various positions, and taking the two curves as the boundaries of a groove cut into the metal. A familiar application of the use of a heart-shaped cam may be found in the bobbin-winder of the domestic sewing machine. The thread is fed to and fro at a uniform rate, the follower of the cam acting as a guide for the thread. The action is made positive by the employment of two follower rollers.

Effect of Changing Location of Cam Roller. — When the line of motion of a follower passes through the center of rotation of the cam, and the angle of the curve causes it to work hard, the curve may be modified, and the same motion of

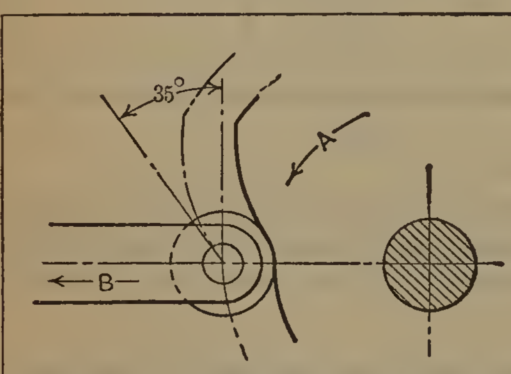

Fig. 3

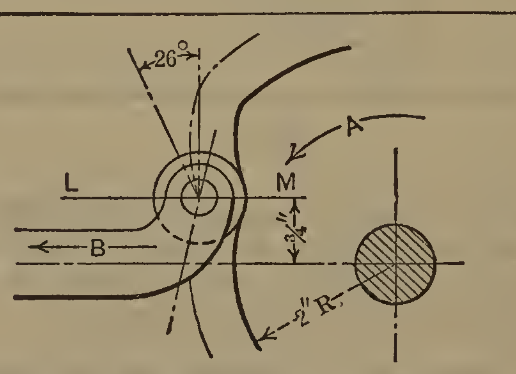

Fig. 4

follower obtained by placing the follower with its line of action parallel to its original position and not passing through the center of the cam. A condition may be assumed, as shown in Fig. 3. Here the cam rotates in the direction indicated by arrow *A*. It moves the follower ¾ inch in the direction indicated by arrow *B*, during a 30-degree angle of motion of the cam-shaft. The angle of the cam presented to the follower at the beginning of the stroke would be 35 degrees, as determined by the tangent to the curve. Should the cam curve work hard at the required speed, the cam would be made of greater diameter, if possible, which would reduce the angle of the cam. The design of the machine, however, might make this change impossible. Another way consists in changing the location of the cam roller. In Fig. 4 all conditions are the same as in Fig. 3, except that the roller has been placed ¾ inch above the line passing through the center of the cam. The center of the roller will now pass along the line *LM*, or parallel to the line of motion in Fig. 3. The angle of the curve presented to the roller in this case is 26 degrees — much less than the angle in Fig. 3 — and the angle decreases as the roller moves away from the center of rotation. There is, of course, a limit to the distance the roller may be changed, for if placed too far away from the center line, the thrust in the direction at right angles to the direction of motion of the follower would be so great as to offset the advantage gained. Even without the aid of an illustration it may be seen that to place the cam roller on the other side of the center would cause the angle of the cam curve to increase, thus making conditions worse. The offset of the roller should be in the direction opposed to the direction of motion of the cam.

Laying-out a Uniformly Accelerated Motion Cam. — When a uniformly accelerated motion is used, the distances passed through by the follower during equal periods of time increase uniformly, so that if, for instance, the follower moves a distance equal to 1 length unit during the first second, and 3 during the second, it will move 5 length units during the third second, 7 during the fourth, 9 during

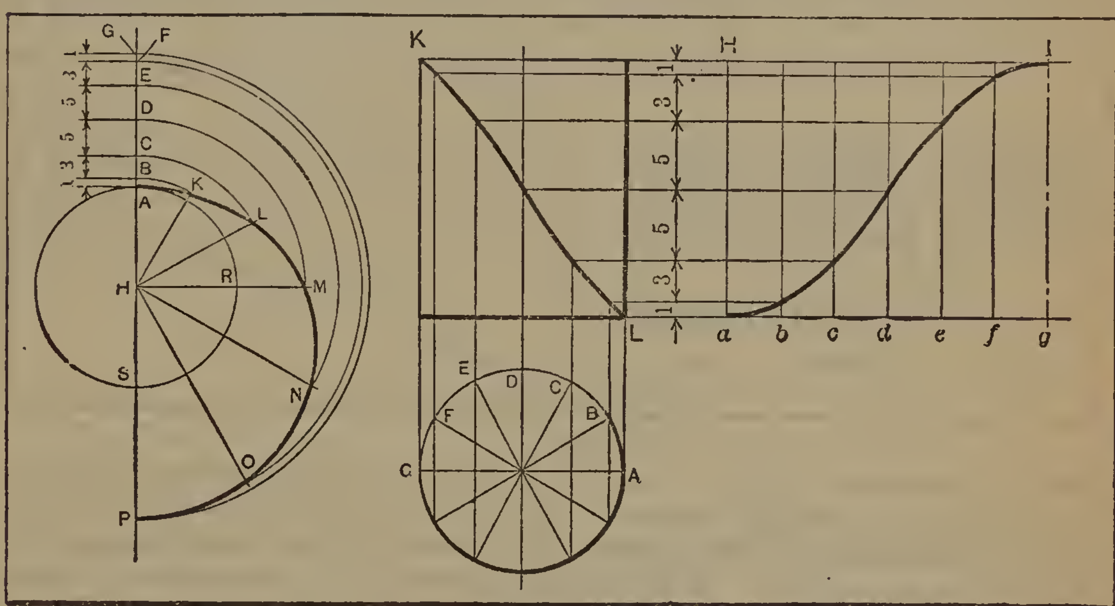

Fig. 5 Fig. 6

the fifth, and so on. When the motion is retarded, it will move 9, 7, 5, 3 and 1 length units during successive seconds. In Fig. 5 is shown a layout of a uniformly accelerated motion plate cam. The motion of the follower is back and forth from *A* to *G*. The rise takes place during 180 degrees and the fall during an equal period, the two halves of the cam being alike. To construct the cam, divide the half circle *ARS* into six equal parts, and draw radii *HK*, *HL*, etc. Divide *AG* into two equal parts, *AD* and *DG*, and then divide each of these parts into three divisions, the lengths of which are to each other as 1 : 3 : 5. With *H* as a center, draw circular arcs from *B*, *C*, *D*, etc., to *K*, *L*, *M*, etc. The intersections between the circles and the radii are points on the cam curve. If the half circle *ARS* should be divided into eight equal parts instead of six, line *AG* would also have to be divided into eight parts in the proportions 1 : 3 : 5 : 7 : 7 : 5 : 3 : 1. With a cam constructed in this manner, the follower starts at A with a velocity of zero; it reaches its maximum velocity at D, and at G, where the motion is reversed, the velocity is again zero.

Development and Layout of a Uniformly Accelerated Motion Cylindrical Cam. — To the right in Fig. 6 is shown the development of a uniformly accelerated motion cam curve laid out on the surface of a cylindrical cam. This development is necessary for finding the projection on the cylindrical surface, as shown at KL. To construct the developed curve, first divide the base circle of the cylinder into, say, twelve equal parts. Set off these parts along line ag. Only one-half of the layout has been shown, as the other half is constructed in the same manner, except that the curve is here falling instead of rising. Divide line aH into the same number of divisions as the half circle, the divisions being in the proportion 1 : 3 : 5 : 5 : 3 : 1. Draw horizontal lines from these division points and vertical lines from a, b, c, etc. The intersections between the two sets of lines are points on the developed cam curve. These points are transferred to the cylindrical surface at the left by projection in the usual manner.

Shape of Rolls for Cylinder Cams. — The rolls for cylindrical cams working in a groove in the cam should be conical rather than cylindrical in shape, in order that they may rotate freely and without excessive friction. Fig. 1 shows a straight roll and groove, the action of which is faulty because of the varying surface speed at the top and bottom of the groove. Fig. 2 shows a roll with curved surface. For heavy work, however, the small bearing area is quickly worn down and the roll

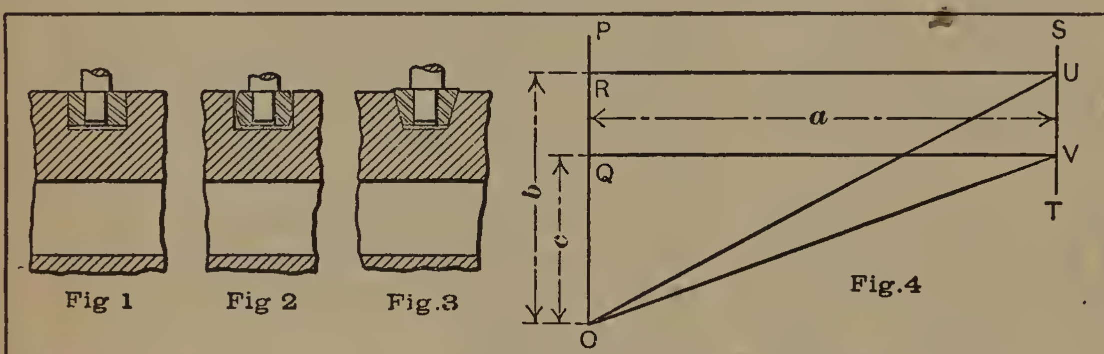

Fig 1 Fig 2 Fig.3 Fig.4

presses a groove into the side of the cam as well, thus destroying the accuracy of the movement and creating backlash. Fig. 3 shows the conical shape which permits a true rolling action in the groove. The amount of taper depends on the angle of spiral of the cam groove. As this angle, as a rule, is not constant for the whole movement, the roll and groove should be designed to meet the requirements on that section of the cam where the heaviest duty is performed. Frequently the cam groove is of a nearly even spiral angle for a considerable length. The method for determining the angle of the roll and groove to work correctly during the important part of the cycle is as follows:

In Fig. 4, b is the circumferential distance on the surface of the cam that includes the section of the groove for which correct rolling action is required. The throw of the cam for this circumferential movement is a. Line OU is the development of the movement of the cam roll during the given part of the cycle, and c is the movement corresponding to b, but on a circle the diameter of which is equal to that of the cam at the bottom of the groove. With the same throw a as before, the line OV will be the development of the cam at the bottom of the groove. OU then is the length of the helix traveled by the top of the roll, while OV is the travel at the bottom of the groove. If then the top width and bottom width of the groove be made proportional to OU and OV, the groove will be properly proportioned.

Cam Rolls and Roll Studs. — It is important that the cam roll and roll stud be ground all over after hardening. The end of the roller should be cut back or recessed 1/64 of an inch or thereabouts on the sides for some distance, beginning at the periphery, so as to avoid undue friction against the collar of the stud or the part in which it is mounted. On account of the warping that takes place in hardening, rolls that are not ground both on the inside and on the outside often will stop under heavy load, until in time flat spots are worn on the face, and then the working surface of the cam will begin to wear or is roughed up. Roll studs that are out of parallel with the working surface of the cam, even to a very small degree, also cause trouble. The same difficulty is met with on cylinder or barrel cams if the milling cutter is set below or above the center of the cam when cutting it. The roll will then bear at one end only at the most important time — when the throw takes place.

There is a great deal of end pressure on the conical rolls used in barrel cams, and this must be taken care of by thrust collars on the studs on which the rolls are mounted, or, better still, by a ball race scored in the collar and the large end of the roll, so as to provide for a ball thrust bearing. The end pressure on a conical roll, however, reduces the side pressure on the stud to a considerable extent, so that the stud may be made shorter or smaller in diameter than when a roll with parallel sides is used.

Cam Milling. — Plate cams having a constant rise, such as are used on automatic screw machines, can be cut in a universal milling machine, with the spiral head either in a vertical position or set at an angle α, as shown by the illustration. When the spiral head is set vertical, the "lead" of the cam (or its rise for one complete revolution) is the same as the lead for which the machine is geared; but when the spiral head and cutter are inclined, any lead or rise of the cam can be obtained, provided it is less than the lead for which the machine is geared, that is, less than the forward feed of the table for one turn of the spiral-head spindle. The cam lead, then, can be varied within certain limits by simply changing the inclination α of the spiral head and cutter. In the following formulas for determining this angle of inclination, for a given rise of cam and with the machine geared for a certain lead, let

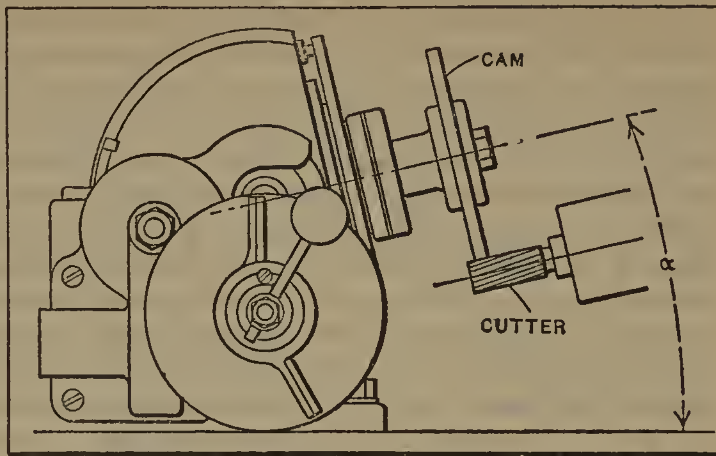
α = angle to which index head and milling attachment are set;
r = rise of cam in given part of circumference;
R = "lead" of cam, or rise if latter were continued at given rate for one complete revolution;
L = spiral lead for which milling machine is geared;
N = part of circumference in which rise is required, expressed as a decimal in hundredths of cam circumference.

$$\sin\alpha = \frac{R}{L}, \text{ and } R = \frac{r}{N}; \text{ hence, } \sin\alpha = \frac{r}{N \times L}$$

For example, suppose a cam is to be milled having a rise of 0.125 inch in 300 degrees or in 0.83 of the circumference, and that the machine is geared for the smallest possible lead, or 0.67 inch; then:

$$\sin\alpha = \frac{r}{N \times L} = \frac{0.125}{0.83 \times 0.67} = 0.2247,$$

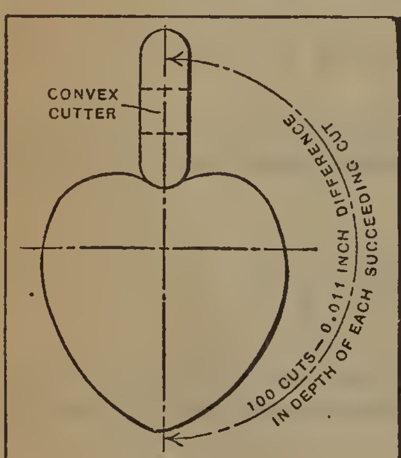
which is approximately the sine of 13 degrees. Therefore, to secure a rise of 0.125 inch with the machine geared for 0.67 inch lead, the spiral head is elevated to an angle of 13 degrees and the vertical milling attachment is also swiveled around to locate the cutter in line with the spiral-head spindle, so that the edge of the finished cam will be parallel to its axis of rotation. When there are several lobes on a cam, having different leads, the machine can be geared for a lead somewhat in excess of the greatest lead on the cam, and then all the lobes can be milled without changing the spiral head gearing, by simply varying the angle of the spiral head and cutter to suit the different cam leads. Whenever possible, it is advisable to mill on the under side of the cam, as there is less interference from chips; moreover, it is easier to see any lines that may be laid out on the cam face. To set the cam for a new cut, it is first turned back by operating the handle of the table feed screw, after which the index crank is disengaged from the plate and turned the required amount.



The accompanying tables give the combinations of change gears and the angular setting required for cutting a cam of any lead likely to be met with in practice. The figures in the column headed "Lead of Cam," represent the rise for one complete revolution. Set the vertical attachment to the angle given in the table. For the dividing head, subtract the angle in the table from 90 degrees; the difference is the angle to which the spindle must be raised from the horizontal position.

Example: — If the angle is 39½ degrees, set the spindle of the vertical attachment 39½ degrees from the vertical. Set the dividing head 50½ degrees from the horizontal position (90 − 39½ = 50½). These tables were compiled by the Cincinnati Milling Machine Co.

Simple Method for Cutting Uniform Motion Cams. — Cams are generally laid out with dividers, machined and filed to the line; but for a cam that must advance a certain number of thousandths per revolution of spindle this method is not accurate. Cams are easily and accurately cut in the following manner. Let it be required to make the heart cam shown in the illustration. The throw of this cam is 1.1 inch. Now, by setting the index on the milling machine to cut 200 teeth and also dividing 1.1 inch by 100, we find that we have 0.011 inch to recede from or advance towards the cam center for each cut across the cam. Placing the cam securely on an arbor, and the latter between the centers of the milling machine, and using a convex cutter set the proper distance from the center of the arbor, make the first cut across the cam. Then, by lowering the milling machine knee 0.011 inch and turning the index pin the proper number of holes on the index plate, take the next cut and so on. Each cut should be marked on paper so that there will be no mistake as to the number of cuts taken; when 100 cuts have been made, the knee must be raised in order to complete the opposite side of the cam.



This method can also be used to advantage for milling uniform motion cam lobes extending only over a portion of the cam circumference. After the milling has been completed, the surface of the cam must be smoothed off by means of filing.

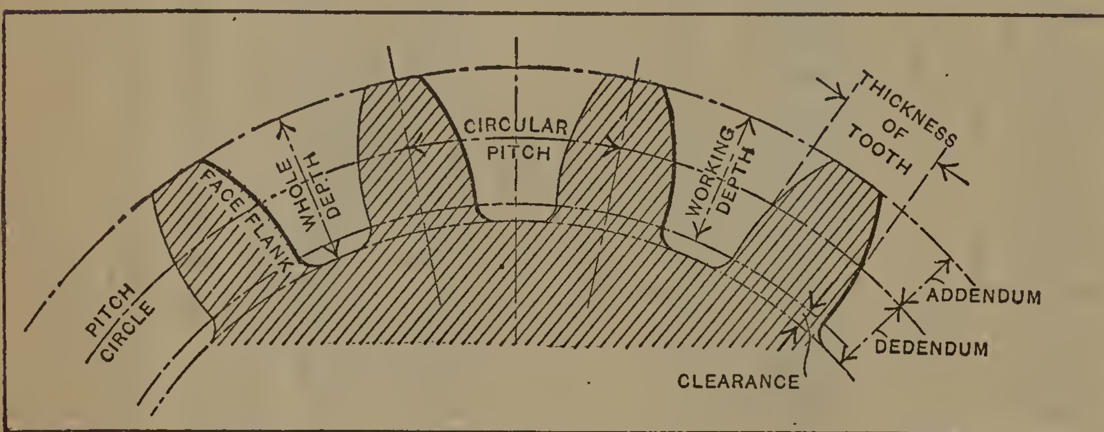
GEARING

Spur Gearing

Systems of Spur Gearing. — Definitions. — Two systems of gear teeth are used for spur gearing: the *cycloidal* and the *involute*. Of these the involute system is the one most commonly used, especially for cut gearing. The standard involute gear tooth has a 14½-degree pressure angle; hence, the rack meshing with gears cut according to this standard has straight sides inclined 14½ degrees from the vertical. In the table of "Rules and Formulas for Dimensions of Spur Gears," the notation below is used:

P = diametral pitch;
P' = circular pitch;
N = number of teeth; (if the number of teeth in both gear and pinion are referred to, N_g = number of teeth in gear, and N_p = number of teeth in pinion);
D = pitch diameter;
C = center distance;
S = addendum;
F = clearance;
W = whole depth of tooth;
T = thickness of tooth;
O = outside diameter of gear.



Gear Tooth Parts

The *circular pitch* is defined as the distance from center to center of two adjacent teeth along the pitch circle. The *diametral pitch* is a number found by dividing the number of teeth by the pitch diameter. In other words, it gives the number of teeth for each inch of pitch diameter.

Cutters for Cutting Gear Teeth

Involute System		Cycloidal System					
No. of Cutter	Number of Teeth	Letter of Cutter	Number of Teeth	Letter of Cutter	Number of Teeth	Letter of Cutter	Number of Teeth
1	135 to rack	*A*	12	*I*	20	*Q*	43 to 49
2	55 to 134	*B*	13	*J*	21 to 22	*R*	50 to 59

8	12 to 13	*H*	19	*P*	38 to 42	*X*	Rack

Rules and Formulas for Dimensions of Spur Gears

No. of Rule	To Find	Rule	Formula
1	Diametral Pitch	Divide 3.1416 by circular pitch.	$P = \frac{3.1416}{P'}$
2	Circular Pitch	Divide 3.1416 by diametral pitch.	$P' = \frac{3.1416}{P}$
3	Pitch Diameter	Divide number of teeth by diametral pitch.	$D = \frac{N}{P}$
4	Pitch Diameter	Multiply number of teeth by circular pitch and divide the product by 3.1416.	$D = \frac{NP'}{3.1416}$
5	Center Distance	Add the number of teeth in both gears and divide the sum by two times the diametral pitch.	$C = \frac{N_g + N_p}{2P}$
6	Center Distance	Multiply the sum of the number of teeth in both gears by circular pitch and divide the product by 6.2832.	$C = \frac{(N_g + N_p)P'}{6.2832}$
7	Addendum	Divide 1 by diametral pitch.	$S = \frac{1}{P}$
8	Addendum	Divide circular pitch by 3.1416.	$S = \frac{P'}{3.1416}$
9	Clearance	Divide 0.157 by diametral pitch.	$F = \frac{0.157}{P}$
10	Clearance	Divide circular pitch by 20.	$F = \frac{P'}{20}$
11	Whole Depth of Tooth	Divide 2.157 by diametral pitch.	$W = \frac{2.157}{P}$
12	Whole Depth of Tooth	Multiply 0.6866 by circular pitch.	$W = 0.6866\,P'$
13	Thickness of Tooth	Divide 1.5708 by diametral pitch.	$T = \frac{1.5708}{P}$
14	Thickness of Tooth	Divide circular pitch by 2.	$T = \frac{P'}{2}$
15	Outside Diameter	Add 2 to the number of teeth and divide the sum by diametral pitch.	$O = \frac{N+2}{P}$
16	Outside Diameter	Multiply the sum of the number of teeth plus 2 by circular pitch and divide the product by 3.1416.	$O = \frac{(N+2)P'}{3.1416}$
17	Diametral Pitch	Divide number of teeth by pitch diameter.	$P = \frac{N}{D}$
18	Circular Pitch	Multiply pitch diameter by 3.1416 and divide by number of teeth.	$P' = \frac{3.1416\,D}{N}$
19	Pitch Diameter	Subtract two times the addendum from outside diameter.	$D = O - 2S$
20	Number of Teeth	Multiply pitch diameter by diametral pitch.	$N = P \times D$
21	Number of Teeth	Multiply pitch diameter by 3.1416 and divide the product by circular pitch.	$N = \frac{3.1416\,D}{P'}$
22	Outside Diameter	Add two times the addendum to the pitch diameter.	$O = D + 2S$
23	Length of Rack	Multiply number of teeth in rack by 3.1416 and divide by diametral pitch.	$L = \frac{3.1416\,N}{P}$
24	Length of Rack	Multiply the number of teeth in the rack by circular pitch.	$L = NP'$

GEARING

According to the system for cutting gear teeth adopted by the Brown & Sharpe Mfg. Co., any gear of one pitch will mesh with any other gear or with a rack of the same pitch. For cutting involute gear teeth, eight cutters are required for each pitch. These cutters are adapted to cut from a pinion of 12 teeth to a rack, and are numbered as shown in the table of "Cutters for Cutting Gear Teeth."

Cutters for the cycloidal form of teeth are also made so that a gear of any pitch will mesh into any other gear or into a rack of the same pitch, but twenty-four cutters are required for each pitch. In order that gears with this form of tooth shall run well together, they must be cut accurately to the exact depth. To secure the proper depth of tooth, the cutters are made with a shoulder determining the required depth. The twenty-four cutters for the cycloidal form of teeth are designated by letters A, B, C, etc. A list of these cutters is also given in the table.

Internal Spur Gears. — The dimensions for internal spur gears may be found by the same formulas as those for external spur gears, except for the modifications made necessary by the fact that the center distance in internal gearing is equal to the *difference* between the two pitch radii, instead of their *sum*. In addition, the term "inside diameter" (I in the table of dimensions of internal spur gears) takes the place of the outside diameter of external spur gearing. This diameter, of course, is the diameter of the hole in the blank before the teeth are cut. In laying out the shape of teeth for internal gearing, interferences are almost sure to be met with. The points of internal gear teeth must, therefore, be relieved to avoid interference with the flanks of the meshing teeth. Interference occurs also when the pinion has too nearly the same number of teeth as the gear. In this case, there is a tendency for the points of the pinion and the gear teeth to strike as they roll into and out of engagement. To avoid this interference, the teeth must be cut by specially made cutters or shaped on a gear shaping machine.

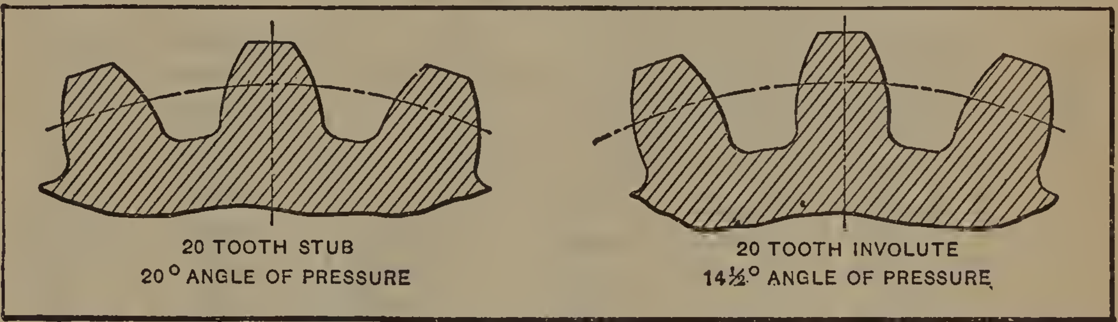
Rules and Formulas for Internal Spur Gears

(Where rules and formulas are not given, they are the same as for external gears)

No. of Rule	To Find	Rule	Formula
5	Center Distance	Subtract the number of teeth in the pinion from the number of teeth in the gear and divide the remainder by 2 times the diametral pitch.	$C = \frac{N_g - N_p}{2P}$
6	Center Distance	Multiply the difference of the numbers of teeth in the gear and pinion by the circular pitch and divide the product by 6.2832.	$C = \frac{(N_g - N_p)\,P'}{6.2832}$
15	Inside Diameter	Subtract 2 from the number of teeth and divide the remainder by the diametral pitch.	$I = \frac{N - 2}{P}$
16	Inside Diameter	Subtract 2 from the number of teeth, multiply the remainder by the circular pitch, and divide the product by 3.1416.	$I = \frac{(N - 2)\,P'}{3.1416}$
19	Pitch Diameter	Add twice the addendum to the inside diameter.	$D = I + 2S$
22	Inside Diameter	Subtract twice the addendum from the pitch diameter.	$I = D - 2S$

The Stub Gear Tooth. — The stub gear tooth has been applied successfully, particularly to automobile drives. This gear tooth has a shorter addendum and dedendum than the ordinary involute tooth, and the pressure angle is 20 degrees instead of 14½, as in the ordinary standard. There are two systems of these teeth in use, tables for both of which are given herewith. (See "Dimensions of Stub Gear Teeth" and the following tables arranged according to both diametral and circular pitches.)

The proportions of the stub gear teeth introduced by Fellows Gear Shaper Co. are based on the use of two diametral pitches. One diametral pitch, say 8, is used as the basis for obtaining the dimensions for the addendum and dedendum,



Comparison between Stub Gear Teeth and Standard Involute Teeth

while another diametral pitch, say 6, is used for obtaining the dimensions of the thickness of the tooth, the number of teeth, and the pitch diameter. Teeth made according to this system are designated as 6/8 pitch, 12/14 pitch, etc., the numerator in this fraction indicating the pitch determining the thickness of the tooth and the number of teeth, and the denominator, the pitch determining the depth of the tooth. The clearance is made greater than in the ordinary gear-tooth system and equals 0.25 ÷ the denominator of the diametral pitch.

Dimensions of Stub Gear Teeth (Fellows Gear Shaper Co.'s System)

Diametral Pitch	Thickness of Tooth	Addendum	Working Depth	Depth of Space below Pitch Line	Clearance	Whole Depth of Tooth
4/5	0.3927	0.2000	0.4000	0.2500	0.0500	0.4500
5/7	0.3142	0.1429	0.2858	0.1786	0.0357	0.3214
6/8	0.2618	0.1250	0.2500	0.1562	0.0312	0.2812
7/9	0.2244	0.1111	0.2222	0.1389	0.0278	0.2500
8/10	0.1963	0.1000	0.2000	0.1250	0.0250	0.2250
9/11	0.1745	0.0909	0.1818	0.1136	0.0227	0.2045
10/12	0.1571	0.0833	0.1667	0.1041	0.0208	0.1875
12/14	0.1309	0.0714	0.1429	0.0893	0.0179	0.1607

In the other system for stub gear teeth (originated by the R. D. Nuttall Co.), the tooth dimensions are based directly upon the circular pitch. The addendum is made 0.250 × the circular pitch, and the dedendum, 0.300 × the circular pitch.

The advantages of the stub gear tooth may be stated as follows: 1. Greater strength. 2. Equal arc of rolling contact as in the 14½-degree involute gear. 3. Extreme sliding contact avoided. 4. More even wearing contact. If the teeth are milled a greater number of rotary cutters are required to cover a given range of teeth. While only eight cutters are required for each pitch in the standard involute system, fifteen cutters are recommended for stub-tooth gears of equal accuracy.

When a generating machine, such as the Fellows gear shaper, is used, only one cutter is required for each pitch, on account of the cutting action of this machine.

Strength of Stub Tooth. — As a general rule, stub-tooth pinions with less than 25 teeth are about 25 per cent stronger than the standard 20-degree involute, and 40 per cent stronger than the standard 14½-degree involute tooth. For larger gears, the difference is in favor of the stub tooth, but is not quite so marked.

Diametral Pitch Gear Tooth Parts for Stub Teeth (Nuttall System)

Clearance of Gears Cut on the Gear Shaper. — When gears are cut on the gear shaper, the clearance is made equal to 0.25 ÷ diametral pitch. Hence the root diameter of these gears is smaller than the root diameter of ordinary milled gears. A table is given (page 624) of root diameters of gears cut on the gear shaper. The pitch and outside (blank) diameters are the same as for ordinary milled gears, and the tables, "Pitch Diameters of Diametral Pitch Gears," and "Outside Diameters of Diametral Pitch Gears," apply to gears cut on the gear shaper also.

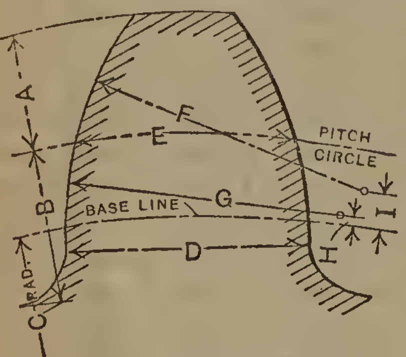
Special Tooth Shape for Rolling Mill Gears. — The illustration and table below give data for laying out special 22½-degree involute gears for rolling mill service. These teeth vary somewhat from the standard shape, and liberal fillets are provided at the root of the teeth to prevent breakage due to sharp corners at these points. The dimensions given in the table are for 1-inch circular pitch. To find the dimensions for any other pitch, multiply the dimension given by the circular pitch. The length of the face of rolling mill pinions is made about equal to the pitch diameter. The angle of the tooth with a line parallel to the axis of the gear is usually made 30 degrees. The figures given in the column headed "Strength for 1-inch Pitch, 1-inch Face" are based on a working stress of 1000 pounds per square inch. To find the strength of teeth for other dimensions and other working stresses, multiply the figures given by: face of gear × circular pitch × $\frac{\text{working stress}}{1000}$.

Example: — Find allowable pressure on teeth with a working stress of 4000 pounds per square inch, for a 2-inch circular pitch gear of 4-inch face having 20 teeth.

$$136 \times 4 \times 2 \times \frac{4000}{1000} = 4352 \text{ pounds.}$$

Rolling Mill Gear Teeth



Formulas:

$A = 0.275 \times$ circular pitch;
$B = 0.325 \times$ circular pitch;
$C = 0.462 \times$ pitch diameter;
$E = 0.49 \times$ circular pitch;
$F = 0.251 \times$ pitch diameter;
$G = 0.136 \times$ pitch diameter;
Pressure angle = 22½ degrees.

Grant's Odontograph. — The table entitled "Grant's Odontograph" provides a simple means for laying out accurately shaped gear teeth by means of circular arcs which very closely approximate the exact tooth curves. The method was devised by Mr. George B. Grant, and differs for cycloidal and involute teeth.

Odontograph for Cycloidal System. — First draw the pitch, addendum, root and clearance circles and space off the pitch of the teeth on the pitch circle in the usual way. Then draw the circle marked "line of flank centers" at the distance d, as given in the table, outside of the pitch line and draw the "line of face centers" at the distance D inside of it. With the face radius R in the dividers, draw in all the face curves from centers on the "line of face centers"; then with the flank radius r draw all the flank curves from centers on the "line of flank centers."

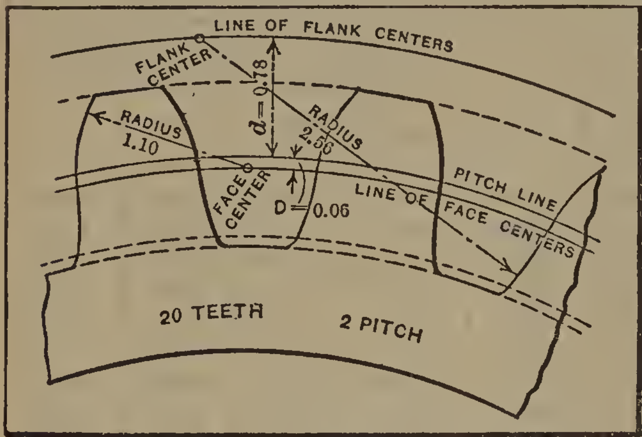

Fig. 1

The table gives the distances D and d and radii R and r, for pitches either exactly 1 diametral or 1 inch circular pitch. For any other pitch, divide or multiply as directed in the table. The illustration, Fig. 1, shows the method applied to laying out a two diametral pitch gear. The odontograph may also be applied to laying out teeth for internal gears.

Odontograph Table for Involute System. — Lay off the pitch, addendum, root and clearance circles and space off the teeth on the pitch line, as indicated in Fig. 2. Draw the "base line" 1/60 of the pitch diameter inside the pitch line. Use the face radius as given in the table for involute teeth for drawing all the faces from the pitch line to the addendum line, the centers being on the "base line." If the pitch is any other than 1 diametral or 1-inch circular pitch, divide or multiply the values given in the table as directed. To draw the flanks of the teeth from the pitch line to the "base line," use the flank radius given, with the center on the "base line." Then draw straight radial flanks from the "base line" to the root line, and round them into the clearance line. The illustration, Fig. 2, shows the method applied to laying out a two diametral pitch gear. The odontograph table for involute teeth can be used for internal gears in the same way as for external gears, but care must be taken that the point of the tooth of the gear is cut off to avoid interference. No correction for interference, however, is needed on the points of the pinion teeth or on the flanks of the gear teeth.

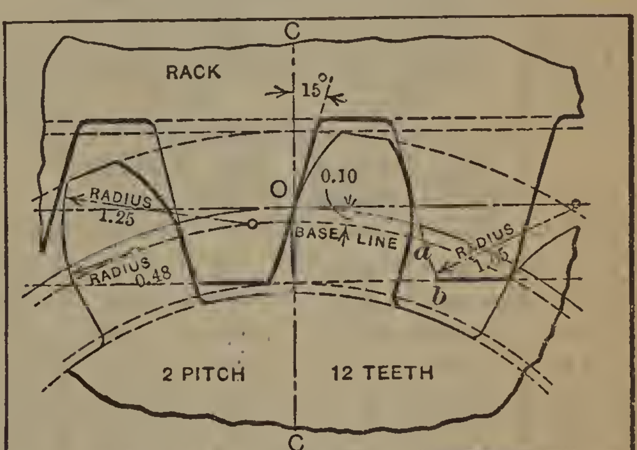

Fig. 2

Special Rule for Involute Rack. — Draw the sides of the rack teeth as straight lines inclined 15 degrees to the center line COC. Draw the outer half ab of the face by means of a circular arc having a radii of 2.10 inches divided by the diametral pitch, or 0.67 inch multiplied by the circular pitch, the center for this arc being on the pitch line of the rack.

Grant's Odontograph

Metric or Module System of Gear Teeth. — In the metric system, the diametral pitch is not used, but instead, the dimensions of gear teeth are expressed by reference to the *module* of the gear. The module is equal to the pitch diameter in millimeters divided by the number of teeth in the gear. For example, if the pitch diameter of a gear is 50 millimeters and the number of teeth, 25, then the module equals $50 \div 25 = 2$. The accompanying table gives a comparison between the module and the corresponding diametral pitch of gears.

The module is also equal to the circular pitch in millimeters divided by 3.1416. Either rule gives the same result.

Module and Corresponding Diametral Pitch

Module	Corresponding English Diametral Pitch	Module	Corresponding English Diametral Pitch	Module	Corresponding English Diametral Pitch	Module	Corresponding English Diametral Pitch

Selecting the Number of Teeth for Gears and Sprockets. — The tables "Gear Ratios and Their Decimal Equivalents" contain the decimal equivalents of all fractions with denominators up to 60. In machine design it is frequently necessary to determine gears or sprockets with low numbers of teeth to give approximately such ratios as can be expressed exactly only with very high numbers. For example, it may be required to have the speeds of the driving and driven gears as nearly as possible to 1149 and 473 revolutions per minute. It may be stipulated, however, that the number of teeth in the larger gear must not exceed 60. Dividing 473 by 1149, we find that the ratio is 0.4117. By referring to the tables, the nearest fractional value to this ratio, with a denominator less than 60, is found to be 7/17; thus, the nearest number of teeth in the gears can be 14 and 34, or 21 and 51. This will give speeds of 1149 and 473.118 revolutions per minute, which introduces a very small error. In the absence of such tables, the method of obtaining the approximate fraction 7/17 would be very cumbersome.

As another example, suppose it is desired to feed stock to a punch press through rolls of 4-inch diameter, the rolls being turned by a ratchet and pawl at the end of each stroke of the punch. The feed is to be as near as possible to 2¼ inches, and the number of teeth in the rachet to be as low as possible. To find the answer to this problem with the aid of the tables, proceed as follows: The feed for one revolution of the rolls is $4\pi = 12.5664$. To feed 2¼ inches, the rolls must make $2.25 \div 12.5664 = 0.1790$ of a revolution. Referring to the table, the nearest fraction to this ratio is 5/28; hence we choose a ratchet gear of 28 teeth, feeding five teeth at a stroke. The feed will be 2.244 inches instead of 2.25 inches, an error of only 0.006 inch. If we should choose the next higher fraction to the ratio 0.1790, which is 7/39, the ratchet would have 39 teeth, and a feed of seven teeth in this ratchet would be equivalent to a feed of 2.256 inches, which also involves an error of 0.006 inch.

Chordal Thicknesses of Gear Teeth at Pitch Line

T = chordal thickness of tooth at pitch line;
H = perpendicular distance from chord to outside circumference of gear (corrected addendum).

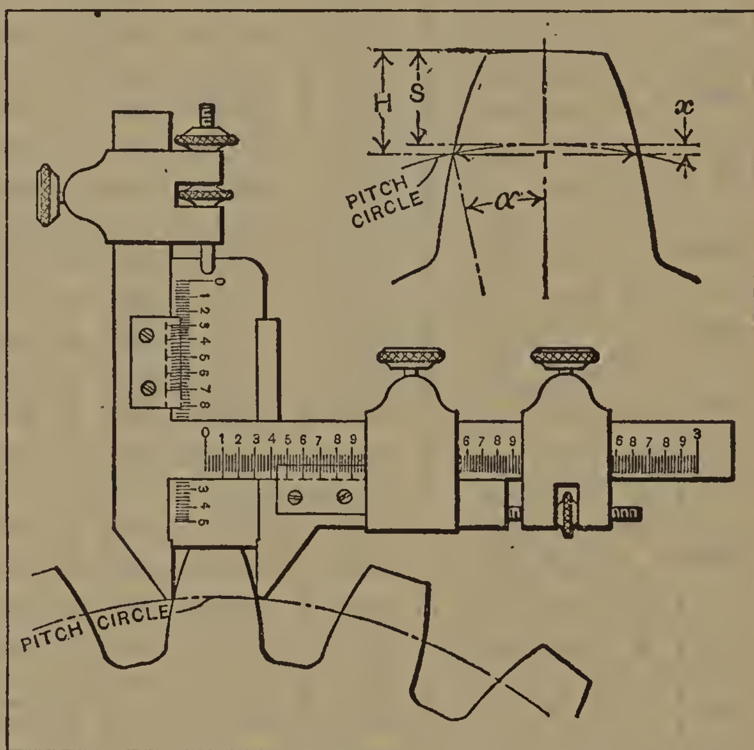
Chordal Thicknesses and Addenda for Gear Teeth and Gear Cutters. — In measuring the thickness of gear teeth, it is necessary to make allowance for the curve of the pitch circle of the gear. The tables of chordal thicknesses for gear cutters and gear teeth give the straight-line distance across the tooth at the pitch circle, and also what is called the "corrected addendum," that is, the perpendicular distance from the chord at the pitch circle to the outside of the gear.

In the case of the gear cutter, the chordal thickness is the same as that for the gear, but the corrected addendum for the gear cutter is different from the corrected addendum for the gear. The two dimensions added together give the total depth of the gear tooth. The tables given are calculated for both diametral and circular pitches and for all commonly used pitches in either system.

Testing the Tooth Thickness when Milling Gear Teeth. — The special vernier gear-tooth caliper illustrated is sometimes used for testing the thickness of the first tooth milled. This test is especially desirable if there is any doubt about the accuracy of the blank diameter. (The outside diameter of a gear blank can be found by adding 2 to the number of teeth and dividing by the diametral pitch.) To test the tooth thickness, a trial cut is taken for a very short distance at one side of the blank; then the work is indexed for the next space, after which another trial cut is taken part way across the gear. The vertical scale of the caliper is set so that when it rests on top of the tooth, as shown, the lower ends of the caliper jaws will be at the height of the pitch circle. The horizontal scale then shows the chordal thickness of the tooth at this point. When a gear tooth is measured in this way, it is the chordal thickness T (see detail of tooth) that is obtained, instead of the thickness along the pitch circle. Hence, when measuring teeth of coarse pitch, especially if the diameter of the gear is quite small, dimension T should be obtained. It is also necessary to find the height x of the arc and add it to the addendum S to obtain the corrected height H, in order to measure the chordal thickness T at the proper point on the sides of the tooth. The table "Chordal Thicknesses of Gear Teeth at Pitch Line" gives this dimension T and corrected height H for various diametral and circular pitches and numbers of teeth.



If α = one-half of the angle subtended from the center of the gear by one gear tooth (see illustration); N = number of teeth in gear; T = chordal thickness of tooth at pitch line; and R = pitch radius of gear; then:

$$\alpha = 90° \div N; \qquad T = 2R \times \sin \alpha.$$

The height x of the arc equals 1 minus the cosine of angle α, multiplied by the pitch radius of the gear, or, expressed as a formula, $x = R\,(1 - \cos\,\alpha)$. The vertical scale of the caliper is set to dimension H or x + addendum S.

Depth of Cut for Milling Spur-gear Teeth. — The whole depth of cut can be found by dividing the constant 2.157 by the diametral pitch of the gear. For example, if the diametral pitch is 12, the depth of the tooth space equals $\frac{2.157}{12}$ = 0.180 inch. The depth of the cut also equals 0.6866 multiplied by the circular pitch. When milling gear teeth that are coarser than 6 or 7 diametral pitch, it is advisable to first rough mill all the teeth, and then take finishing cuts. Special "stocking cutters" are often used for rough milling coarse pitch gears preparatory to finishing by an accurately formed cutter.

Limits for Gearing. — The limits for center distance, pitch diameter and outside diameter of blanks, given in the table below, are applicable to spur gearing used under ordinary conditions. The + sign indicates dimensions over, and the − sign, dimensions under, the actual theoretical dimension.

Manufacturing Limits for Gearing

Diametral Pitch	Center Distance	Pitch Diameter	Blanks, Outside Diameter
16	±0.002	−0.003 to −0.005	0.000 to −0.005
14	±0.003	−0.004 to −0.006	0.000 to −0.005
12	±0.0035	−0.0045 to −0.007	0.000 to −0.006
10	±0.004	−0.005 to −0.008	0.000 to −0.006
8	±0.005	−0.006 to −0.009	0.000 to −0.007
6	±0.006	−0.007 to −0.010	0.000 to −0.008
5	±0.007	−0.008 to −0.011	0.000 to −0.010
4	±0.008	−0.009 to −0.012	0.000 to −0.015

Strength of Gear Teeth. — The method in most common use for determining the strength of gears is the one introduced by Mr. Wilfred Lewis and described by him in a paper read before the Engineers' Club of Philadelphia, October 15, 1892, and published in the proceedings of the club January, 1893. The Lewis formula is directly applicable to cut gears. For cast gears, the best method is to use the Lewis formula so modified as to give a factor of safety two or three times that required by this formula, depending upon the severity of the conditions under which the gears are used. A general rule for cast gears used under varying conditions can, however, hardly be devised.

The accompanying tables of "Rules and Formulas for the Strength of Gear Teeth," "Factors for Calculating the Strength of Gear Teeth" and "Working Stresses used in the Lewis Formula for the Strength of Gear Teeth" make it possible to quickly calculate the strength of spur gears. The formulas and factors given are based on the use of the diametral pitch, and the constants Y given in the factor table are valid only when the diametral pitch is used. If the circular pitch is given, it should be transformed into diametral pitch by dividing 3.1416 by the circular pitch. By means of the formulas given, the horsepower which can be transmitted by a gear of a given pitch diameter and diametral pitch, running at a given number of revolutions per minute, can be found by using Formulas (1) to (4) in the order given. The allowable static unit stress for the material in the gear is selected from the first line (velocity = 0) in the table of working stresses; the stress at any given velocity may also be found directly from the table.

As an example, assume that it is required to find the horsepower which it is permissible to transmit by a spur gear having 15-inch pitch diameter, 4 diametral pitch, making 100 revolutions per minute, and having a width of face of 1½ inch, if made according to the 14½-degree involute system. The gear is made of steel and the allowable static unit stress for the material may, therefore, be assumed to be 15,000 pounds per square inch. First insert the values of the revolutions per

Factors for Calculating Strength of Gear Teeth

Rules and Formulas for the Strength of Gear Teeth

(Based on the Lewis Formula)

D = pitch diameter of gear in ins.;
R = revolutions per minute;
V = velocity in ft. per min. at pitch diameter;
S_s = allowable static unit stress for material;
S = allowable unit stress for material at given velocity;
A = width of face in inches;
Y = outline factor (see table above);
P = diametral pitch (if circular pitch is given, divide 3.1416 by circular pitch to obtain diametral pitch);
W = maximum safe tangential load in pounds at pitch diameter;
H.P. = maximum safe horsepower.

Use rules and Formulas (1) to (4) in the order given.

No.	To Find	Rule	Formula
1	Velocity in feet per min. at the pitch diameter.	Multiply the product of the diameter in inches and the number of revolutions per minute, by 0.262.	$V = 0.262\, DR$
2	Allowable unit stress at given velocity.	Multiply the allowable static stress by 600 and divide the result by the velocity in feet per minute plus 600.	$S = S_s \times \frac{600}{600 + V}$
3	Maximum safe tangential load at pitch diameter.	Multiply together the allowable stress for the given velocity, the width of face, and the tooth outline factor; divide the result by the diametral pitch.	$W = \frac{SAY}{P}$
4	Maximum safe horsepower.	Multiply the safe load at the pitch line by the velocity in feet per minute, and divide the result by 33,000.	$\text{H.P.} = \frac{WV}{33{,}000}$

minute and the pitch diameter in Formula (1), and thus find the velocity in feet per minute at the pitch diameter. This velocity, as found in Formula (1), together with the allowable static unit stress, is then inserted in Formula (2), and the allowable unit stress at the given velocity is then found. This unit stress is now inserted in Formula (3), together with the width of face, the outline factor Y (which is found from the table to be 0.358 for 60 teeth), and the diametral pitch, and in this way the maximum safe tangential load W is found. Finally, by inserting the value of W just found, and the value of V found from Formula (1), in Formula (4), determine the maximum safe horsepower which can be transmitted by the gear.

Working Stresses used in the Lewis Formula for the Strength of Gear Teeth

Velocity in Feet per Minute = V	Strength Factors	Safe Working Unit Stress = S, in Pounds per Square Inch

Simple Formula for Determining Power-transmitting Capacity of Spur Gears. — As electric motors are used more widely for machine and mill drives, the problem of calculating the size of gears required arises more frequently; and as motors are rated according to horsepower and speed in revolutions per minute, it is desirable to rate or calculate gears the same way, rather than to figure the breaking strength of the gears at loads in pounds.

The following formula, which is based on the Lewis formula, has been arranged to simplify this work, especially for those who frequently have to calculate the power-transmitting capacity of gearing. In this formula the notation is the same as given previously under "Rules and Formulas for the Strength of Gear Teeth." The outline factor Y for given number of teeth and pressure angle may be obtained from the table "Factors for Calculating Strength of Gear Teeth."

$$H = \frac{S_S A Y V}{P\ 55\quad (600 + V)}$$

The velocity in feet per minute at pitch line of gear = 0.262 × pitch diameter in inches × R.P.M. In using this formula, the values of S for accurately cut gears made of different materials are as follows: cast iron, 8000; semi-steel, 9000; U. S. Government bronze, 10,000; 0.30 per cent carbon steel, 15,000; 0.50 per cent carbon steel, 25,000; rawhide, 5000; bakelite, condensite, formica, textoil, etc., 5000.

Example: Find the horsepower that can be transmitted safely by a cast-iron spur gear which is to have 40 teeth of 4 diametral pitch, a 2-inch face width, and a speed of 80 R.P.M. It is assumed that the gear has accurately cut teeth, and the pressure angle is 14½ degrees. Then,

$$H = \frac{8000 \times 2 \times 0.34 \times 210}{4 \times 55 \times (600 + 210)} = \frac{80 \times 2 \times 34 \times 210}{4 \times 55 \times 810} = 6.4 \text{ horsepower}$$

It will be noted that the arithmetical work is reduced somewhat simply by dropping the decimal point from the outline factor 0.34 and at the same time cancelling two ciphers from 8000 representing the static unit stress.

Pitch of Gear for Given Power-transmitting Capacity. — The following formulas make it possible to determine directly the diametral or circular pitch of a spur gear when the horsepower to be transmitted and the velocity in feet per minute at the pitch diameter are known. The notation used is the same as given under "Rules and Formulas for the Strength of Gear Teeth."

Let P_1 = circular pitch $= \dfrac{3.1416}{P}$, or $P = \dfrac{3.1416}{P_1}$

By inserting this value in Formula (3) for determining the value of W, we have:

$$W = \frac{P_1 SAY}{3.1416}$$

But A (the width of face) is usually a certain number of times the circular pitch; so that we may write $A = kP_1$, where k generally is from 3 to 4 for gears having cut teeth and from 2 to 3 for cast-teeth gears. Then

$$W = \frac{P_1 SkP_1 Y}{3.1416} = \frac{P_1^2 SkY}{3.1416}$$

From this it follows that

$$P_1 = \sqrt{\frac{3.1416\, W}{SkY}}$$

But $W = \dfrac{33{,}000 \text{ H.P.}}{V}$; Hence, $P_1 = \sqrt{\dfrac{3.1416 \times 33{,}000 \text{ H.P.}}{SkYV}}$

To obtain the diametral pitch P, substitute $\dfrac{3.1416}{P}$ for P_1 and solve for P:

$$P = \sqrt{\frac{3.1416\, SkYV}{33{,}000 \text{ H.P.}}}$$

Rawhide Gears. — Comparatively little information is available as to the strength of rawhide pinions. One prominent maker of rawhide gears makes a regular practice of replacing high-speed cast-iron pinions with those made from rawhide of the same dimensions, providing the peripheral velocity exceeds 1600 feet per minute. When a rawhide pinion is to replace a steel gear, working under severe conditions, a special construction is used in which the weaker material is strengthened by a bronze reinforcement. Rawhide pinions will stand a load of 150 pounds per inch of face for a 1-inch circular pitch gear, with other pitches in proportion, and the load may be increased to a maximum of 250 pounds per inch of face, but it is undesirable to go beyond this limit, owing to the compression of rawhide under heavy loads. Rawhide gears are especially fitted for service where the gear teeth must withstand shocks, and for this reason are suitable for high speeds, as the decrease of the strength of metal gears with increasing velocity is due to the effect of impact.

Horsepower Transmitted by Rawhide Pinions. — The table "Horsepower Transmitted by Rawhide Pinions" gives the power that will be transmitted by a pinion having one-inch face. For gears having other than one-inch face, the value given in the table should be multiplied by the width of face in inches. As an example of the use of the table, assume that a rawhide gear having 20 teeth, 4 diametral pitch, and making 200 revolutions per minute is required to transmit 2 horsepower. What width of face should this gear have in order to safely transmit the power? From the table it is found that a gear of the given dimensions with one inch width of face would safely transmit 0.93 horsepower. A gear $2\frac{1}{4}$ inches wide would then transmit $2\frac{1}{4} \times 0.93 = 2.09$ horsepower. A width of face of $2\frac{1}{4}$ inches would therefore be the correct width.

Horsepower Transmitted by Cast-iron Pinions. — The tables "Horsepower Transmitted by Cast-iron Pinions" are calculated for pinions of one-inch face. For gears having other than one-inch face, the value given in the table should be multiplied by the width of face in inches. As an example of the use of the tables, assume that a cast-iron gear having 20 teeth, 4 diametral pitch, and making 200 revolutions per minute is required to transmit 2 horsepower. What width of face should this gear have in order to safely transmit the power? From the tables it is found that a gear of the given dimensions with one inch width of face would safely transmit 1.48 horsepower per inch width of face. Hence, the gear should be made $1\frac{3}{8}$ inch wide, and will then transmit $1\frac{3}{8} \times 1.48 = 2.035$ horsepower.

Allowance for wear has not been provided in the tables, but has been left to the discretion of the designer. According to Reuleaux the coefficient of wear, C, equals the pressure p on the teeth at the pitch circle in pounds, multiplied by the number of revolutions per minute, N, this product being divided by the width of face A, or, $C = \frac{pN}{A}$. The value of this fraction should never exceed 28,000.

In a pair of cast-iron gears the greatest wear comes on the smallest gear, and while the coefficient of wear should not exceed 28,000 for the largest gear, it may be taken as low as 12,000, if possible without obtaining too large dimensions. To avoid excessive wear on the smaller gear, steel or bronze may be substituted for the pinion.

Tables of Relation between Velocity, Load and Diametral Pitch. — These tables are given for determining the diametral pitches for $14\frac{1}{2}$-degree involute and cycloidal cast-iron gear teeth when the load in pounds per inch width of face, the circumferential velocity, and the number of teeth are given. The speed or circumferential velocity of the teeth, as indicated in the headings of the various tables, is first located; then the load in pounds per inch width of face is found in the column to the left, and the number of teeth located at the top of the tables. The diametral pitch is then obtained from the figures in the body of the tables, opposite the load in pounds and in the column under the teeth. For example, assume that it is required to find the diametral pitch of the teeth in a pinion having 15 teeth, running at a speed of 150 feet per minute, and subjected to a load of 500 pounds per inch width of face at the pitch line. As the speed of the teeth is between 100 and 200 feet per minute, the answer is found in the section thus headed, opposite 500 in the left-hand column, and beneath the heading "14–16 Teeth" at the top of the column. The required diametral pitch of the teeth then is $2\frac{3}{4}$. If the gear is 3 inches wide and subjected at the pitch line to a load of 600 pounds, the load per inch width of face is, of course, 200 pounds, and the diametral pitch for 15 teeth and 150 feet speed would be 7.

The tables can also be used for finding the permissible load in pounds per inch width of face when the diametral pitch and the other factors mentioned are given.

In this case, speed, diametral pitch, and number of teeth are first located and the load is read off in the left-hand column opposite the line in which the given diametral pitch is found. For example, assume that a gear of 8 diametral pitch runs at a speed of 75 feet per minute, the gear having 24 teeth. Locate 8 diametral pitch in the part of the table for 0 to 100 feet per minute, in the column headed "21–25 Teeth," and follow the line in which 8 diametral pitch is given, to the left; the permissible tooth load is 300 pounds per inch width of face. If the gear were only $\frac{3}{4}$ inch wide, then the permissible load, of course, would be $300 \times \frac{3}{4} = 225$ pounds.

General Rules Governing Power-transmitting Capacity of Spur Gears. — In determining the power-transmitting capacity of spur gears having cut teeth, the following general rules should be considered:

1. The horsepower a gear will transmit depends upon the quality of the material, accuracy of the teeth, rigidity of shafts, bearings, and housings, and the accuracy of the shaft alignment.

2. A gear supported on only one side should be made with a comparatively narrow face, a good rule being to make the face width in inches equal to 10 ÷ diametral pitch.

3. Gears should always be made *strong* enough; that is, they should be capable of transmitting at least 25 per cent more than the rated horsepower. The reason for this is that most gearing is subject to overload from one cause or another. If the drive is subject to a known overload, the gears should be made strong enough for the full overload, plus about 25 per cent for safety. Gears for crushers, rolls, and reciprocating pumps must often be made capable of carrying 250 per cent of the normal or rated load.

4. While it is possible to make spur gears with as few as three teeth, small numbers of teeth are not satisfactory for high-speed or hard work. As a general rule, it is not practical to use a pinion with less than 18 teeth, when the pitch-line velocity exceeds 800 feet per minute.

5. When the gears are of rigid construction, mounted on rigid shafts supported on both sides of the gear face, and run in oil, a pitch-line velocity of 2000 feet per minute is permissible in some cases. Usually, however, it is well to keep below 800 feet per minute for metal gears to be used under ordinary conditions. Above 800 feet per minute it is well to use rawhide, bakelite, or some approved type of nonmetallic gear in conjunction with a mating gear made of metal. If noise is not objectionable, both gears may be made of metal. Strength and quietness can be obtained by making the pinion of laminated construction, using alternate plates of steel and bakelite, riveted together.

6. The pitch should be as fine as possible without requiring too wide a face to transmit the power, since the finer pitches tend toward greater efficiency for the gearing.

Proportions of Cast Spur Gears. — The table "Dimensions of Spur Gears" gives the formulas for proportioning cast gears with arms of different cross-sections. This table will prove satisfactory for general conditions, but in individual cases modifications must be made to suit particular designs. The oval arm is the one best adapted for small and medium size gears and gives the best appearance. It requires somewhat more metal for the same strength than the designs shown in the lower part of the table, but it is very easily molded. For large size gears, however, arms of the +, T- and H-sections are largely used. In these designs the metal is so distributed as to give a high degree of rigidity in proportion to the weight; but these forms are more difficult to mold than the oval sections. The H-section, however, is the most desirable for gears, the faces of which are very wide in proportion to their pitch. The draft for removing the pattern from the sand in molding is not shown in the illustrations in the table, but it should be provided for liberally, and should be added to the dimensions given, rather than taken off.

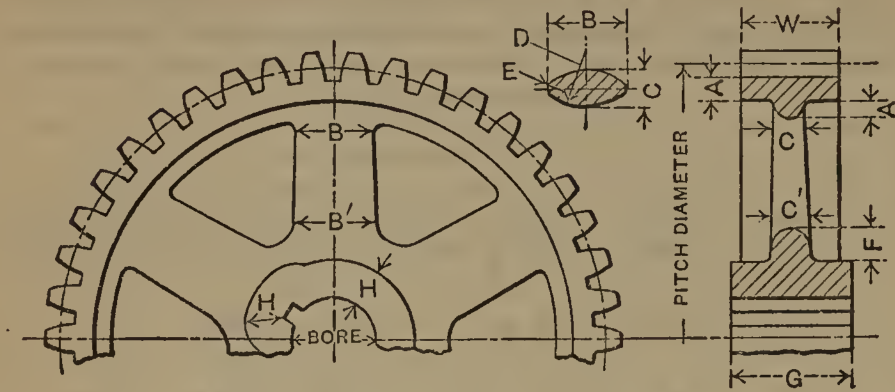
Dimensions of Spur Gears. (See page 644.)

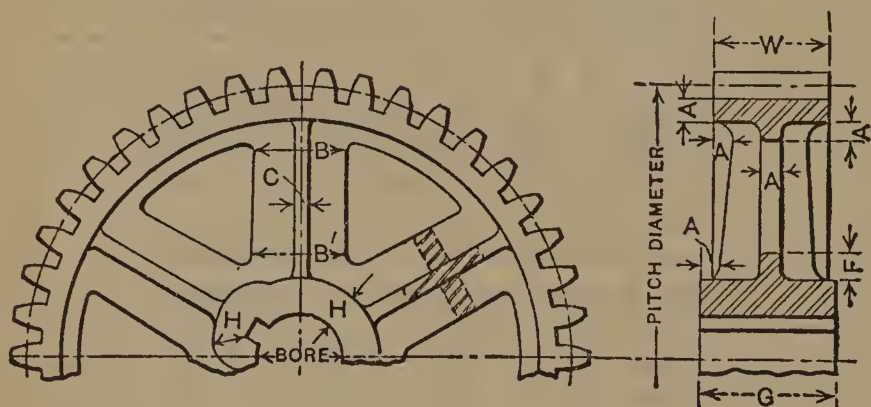
Dimensions of Spur Gears with Oval Arms

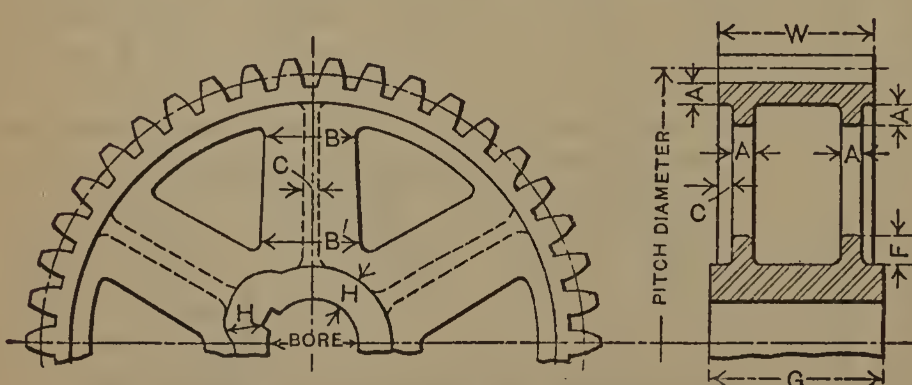


P = diametral pitch, P' = circular pitch.

$A = 1.57 \div P = 0.5\,P'$;
$B = 6.28 \div P = 2.0\,P'$;
$C = 3.14 \div P = P'$;
$D = 4.71 \div P = 1.5\,P'$;
$E = 0.79 \div P = 0.25\,P'$;
$F = 2.00 \div P = 0.65\,P'$;
$G = W + 0.025$ pitch diameter;
$H = 0.44 \times$ bore;
$B' = B + \frac{3}{4}$ inch per foot;
$C' = C + \frac{3}{4}$ inch per foot.

Dimensions of Spur Gears with Ribbed Arms or Arms of H-section

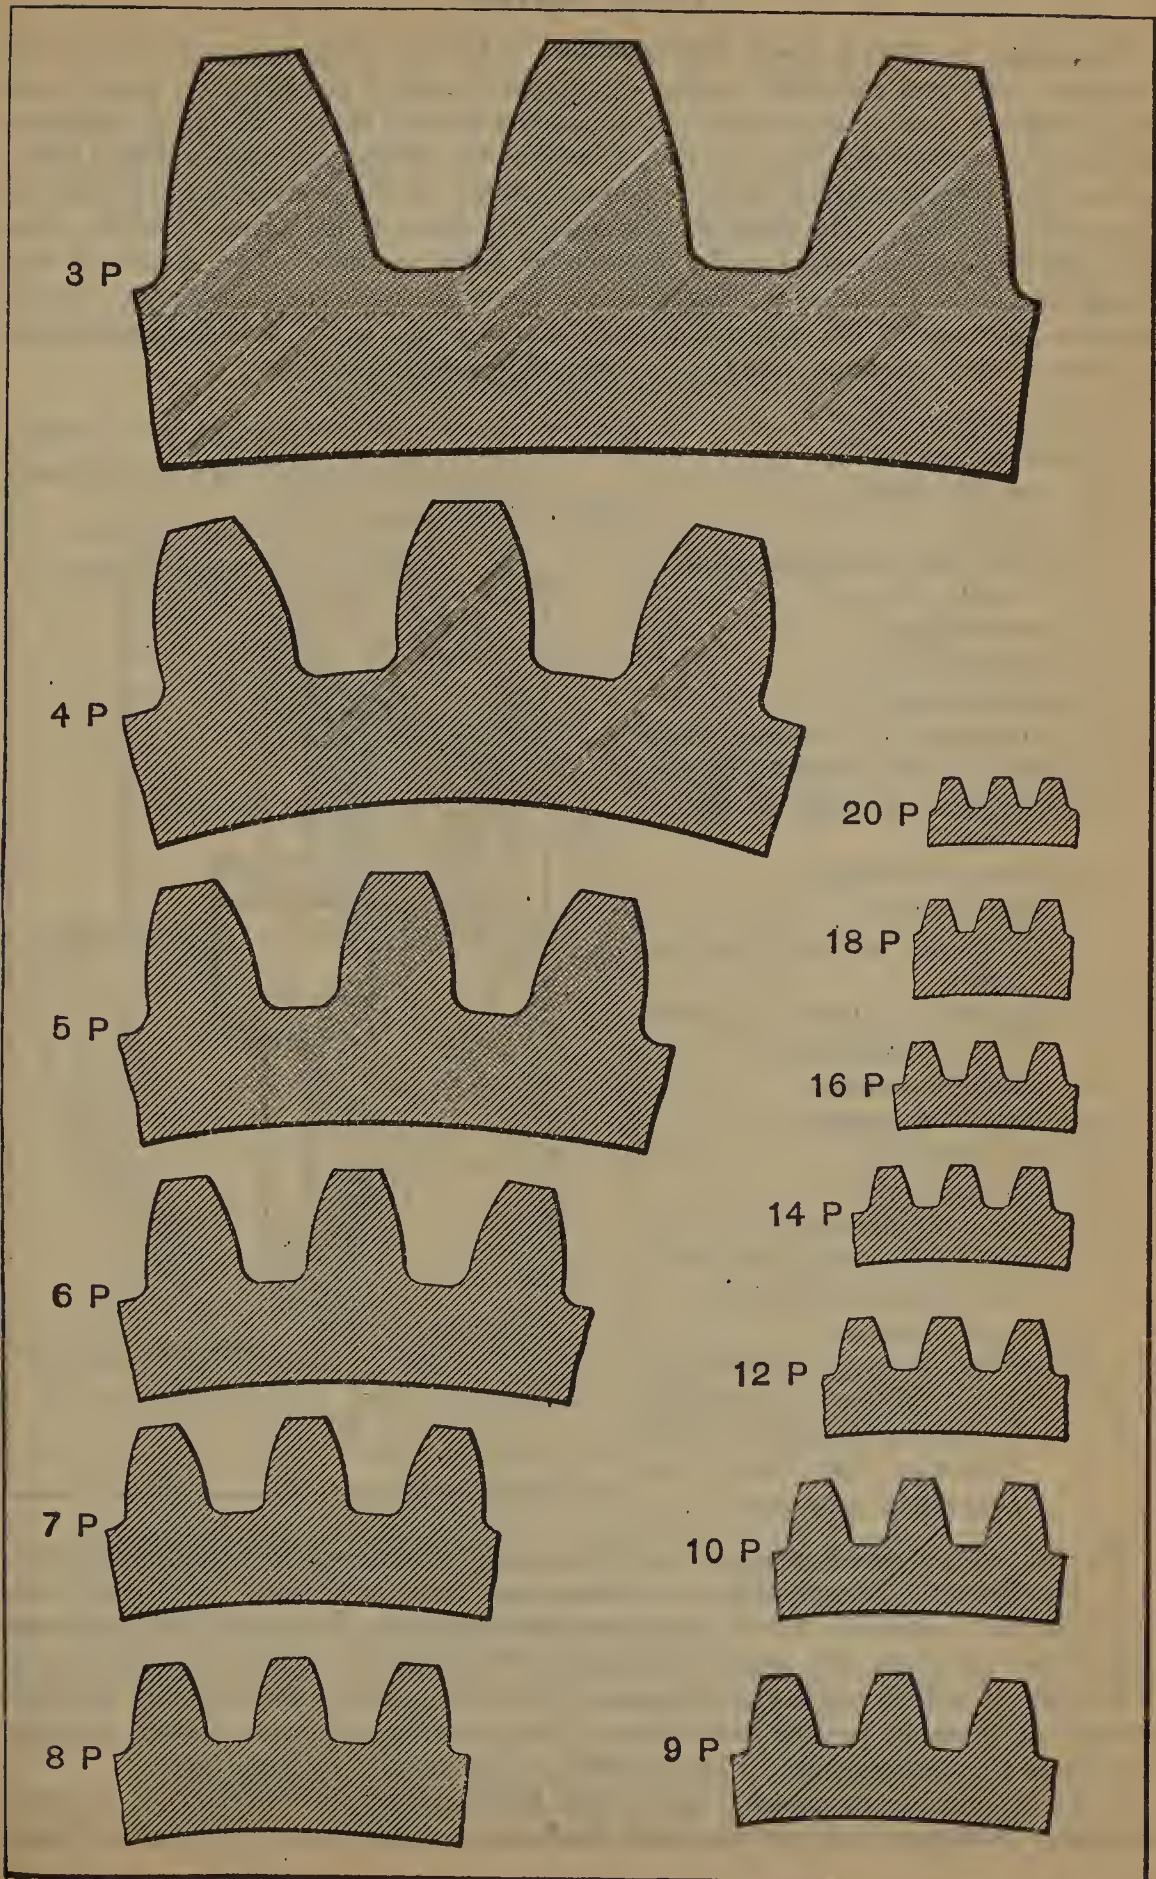




P = diametral pitch, P' = circular pitch.

$A = 1.57 \div P = 0.5\,P'$;
$B = 7.85 \div P = 2.5\,P'$;
$C = 0.94 \div P = 0.3\,P'$;
$F = 2.20 \div P = 0.7\,P'$;
$G = W + 0.025$ pitch diameter;
$H = 0.44 \times$ bore;
$B' = B + \frac{3}{4}$ inch per foot.

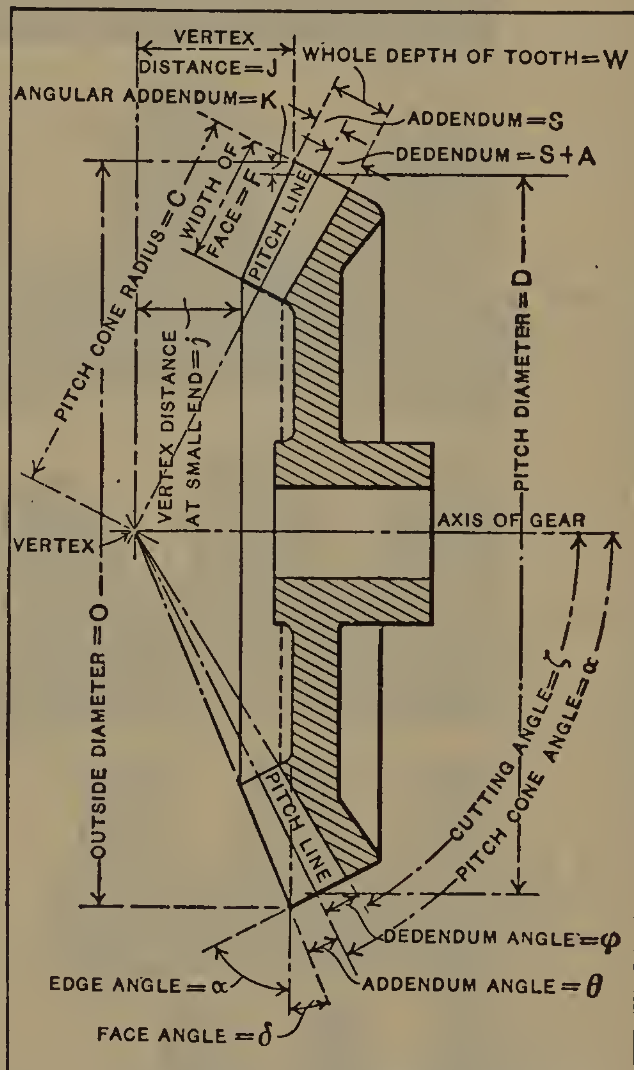
Gear Teeth of Different Diametral Pitch, Full Size



Bevel Gearing

Formulas for Bevel Gear Calculations. — On the following pages are given complete rules and formulas for the calculation of bevel gearing with shafts at a right angle, an acute angle, and an obtuse angle with each other. Separate formulas for miter bevel gearing are also given, as well as for crown gears and internal bevel gears. The numbers given in the left-hand column are for convenient reference to any particular rule. The rules and formulas are given in the order in which they would ordinarily be used by the designer of bevel gearing. The names of the various angles and dimensions referred to in bevel gearing are given in the accompanying engraving. The notation used in the formulas, which is easily understood by comparing the formula with the corresponding rule, is as follows:

N = number of teeth;
P = diametral pitch;
P' = circular pitch;
π = 3.1416;
α = pitch cone angle and edge angle;
γ = center angle;
D = pitch diameter;
S = addendum;
$S+A$ = dedendum (A = clearance);
W = whole depth of tooth space;
T = thickness of tooth at pitch line;
C = pitch cone radius;
F = width of face;
s = addendum at small end of tooth;
t = thickness of tooth at pitch line at small end;
θ = addendum angle;
ϕ = dedendum angle;
δ = face angle;
ζ = cutting angle;
K = angular addendum;
O = outside diameter (edge diameter for internal gears);
J = vertex distance;
j = vertex distance at small end;
N' = number of teeth for which to select cutter, also called "number of teeth in equivalent spur gear."

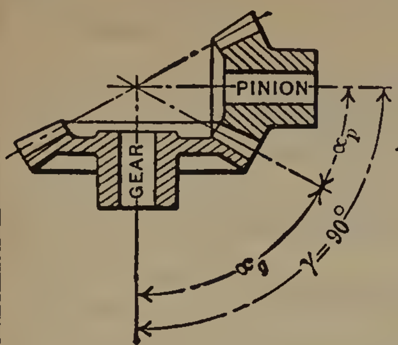


The following exceptions to, and modifications of, the rules given should be noted:

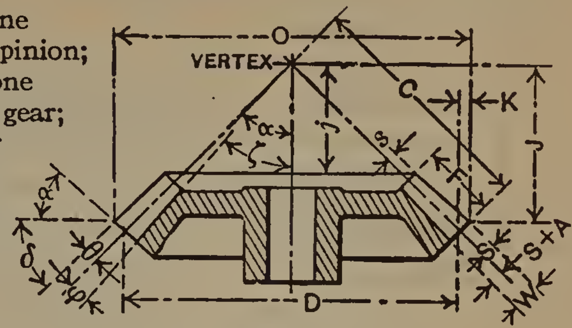
1. The Brown & Sharpe Mfg. Co. recommends that for shaping bevel gear teeth with a formed cutter, the cutting angle be determined by subtracting the *addendum* angle from the pitch cone angle, instead of subtracting the dedendum angle, as in Rule (15). In other words, the clearance at the bottom of the tooth is made uniform instead of tapering toward the vertex. This gives a somewhat closer approximation to the desired shape. This applies, of course, also to Rule (25).

2. In generating machines (such as the Bilgram and the Gleason) it is often advisable to depart from the standard dimensions of gear teeth as given by Rules

Rules and Formulas for Calculating Bevel Gears with Shafts at Right Angles



α_p = Pitch cone angle of pinion;
α_g = Pitch cone angle of gear;
N_p = Number of teeth in pinion, etc.



Use Rules and Formulas Nos. 1 to 21 in the order given.

No.		To Find	Rule	Formula
1		Pitch Cone Angle (or Edge Angle) of Pinion.	Divide the number of teeth in the pinion by the number of teeth in the gear to get the tangent.	$\tan \alpha_p = \frac{N_p}{N_g}$
2		Pitch Cone Angle (or Edge Angle) of Gear.	Divide the number of teeth in the gear by the number of teeth in the pinion to get the tangent.	$\tan \alpha_g = \frac{N_g}{N_p}$
3		Proof of Calculations for Pitch Cone Angles.	The sum of the pitch cone angles of the pinion and gear equals 90 degrees.	$\alpha_p + \alpha_g = 90°$
4		Pitch Diameter.	Divide the number of teeth by the diametral pitch; or multiply the number of teeth by the circular pitch and divide by 3.1416.	$D = \frac{N}{P} = \frac{NP'}{\pi}$
5	These dimensions are the same for both gear and pinion.	Addendum.	Divide 1.0 by the diametral pitch; or multiply the circular pitch by 0.318.	$S = \frac{1.0}{P} = 0.318\,P'$
6		Dedendum.	Divide 1.157 by the diametral pitch; or multiply the circular pitch by 0.368.	$S + A = \frac{1.157}{P} = 0.368\,P'$
7		Whole Depth of Tooth Space.	Divide 2.157 by the diametral pitch; or multiply the circular pitch by 0.687.	$W = \frac{2.157}{P} = 0.687\,P'$
8		Thickness of Tooth at Pitch Line.	Divide 1.571 by the diametral pitch; or divide the circular pitch by 2.	$T = \frac{1.571}{P} = \frac{P'}{2}$
9		Pitch Cone Radius.	Divide the pitch diameter by twice the sine of the pitch cone angle.	$C = \frac{D}{2 \times \sin \alpha}$
10		Addendum of Small End of Tooth.	Subtract the width of face from the pitch cone radius, divide the remainder by the pitch cone radius and multiply by the addendum.	$s = S \times \frac{C - F}{C}$
11		Thickness of Tooth at Pitch Line at Small End.	Subtract the width of face from the pitch cone radius, divide the remainder by the pitch cone radius and multiply by the thickness of the tooth at the pitch line.	$t = T \times \frac{C - F}{C}$
12		Addendum Angle.	Divide the addendum by the pitch cone radius to get the tangent.	$\tan \theta = \frac{S}{C}$
13		Dedendum Angle.	Divide the dedendum by the pitch cone radius to get the tangent.	$\tan \phi = \frac{S + A}{C}$

Rules and Formulas for Calculating Bevel Gears with Shafts at Right Angles

No.	To Find	Rule	Formula
14	Face Angle.	Subtract the sum of the pitch cone and addendum angles from 90 degrees.	$\delta = 90° - (\alpha + \theta)$
15	Cutting Angle.*	Subtract the dedendum angle from the pitch cone angle	$\zeta = \alpha - \phi$
16	Angular Addendum.	Multiply the addendum by the cosine of the pitch cone angle.	$K = S \times \cos \alpha$
17	Outside Diameter.	Add twice the angular addendum to the pitch diameter.	$O = D + 2K$
18	Apex Distance.	Multiply one-half the outside diameter by the tangent of the face angle.	$J = \frac{O}{2} \times \tan \delta$
19	Apex Distance at Small End of Tooth.	Subtract the width of face from the pitch cone radius; divide the remainder by the pitch cone radius and multiply by the apex distance.	$j = J \times \frac{C - F}{C}$
20	Number of Teeth for which to Select Cutter.	Divide the number of teeth by the cosine of the pitch cone angle.	$N' = \frac{N}{\cos \alpha}$
21	Proof of Calculations by Rules Nos. 9, 12, 14, 16 and 17.	The outside diameter equals twice the pitch cone radius multiplied by the cosine of the face angle and divided by the cosine of the addendum angle.	$O = \frac{2C \times \cos \delta}{\cos \theta}$

* See paragraph "Formulas for Bevel Gear Calculations."

and Formulas (1) to (44). For instance, where the pinion is made of bronze and the gear of steel, the teeth of the former can be made wider and those of the latter correspondingly thinner, so as to nearly equalize the strength of the two. Again, where the pinion has few teeth and the gear many, it may be advisable to make the addendum on the pinion larger and the dedendum correspondingly smaller, reversing this on the gear, making the addendum smaller and the dedendum larger. This is done to avoid interference and consequent undercut on the flanks of pinions having a small number of teeth. Such changes are easily effected on generating machines, and instructions for doing this for any case will usually be furnished by the makers of the various machines.

Internal bevel gearing should be avoided except in cases where cast gears would be satisfactory, because it is practically impossible to cut internal bevel gearing. It may be possible to produce internal bevel gears on some forms of templet planing machines, if the pitch cone angle is not too great, but it is impossible on any form of generating machine. Internal bevel gearing can usually be avoided, and be replaced by external bevel gearing, by extending one of the shafts between which motion is to be transmitted, and mounting the gears in such a position that the required motion can be transmitted by a pair of ordinary bevel gears.

Examples of Bevel Gear Calculations. — In the following are given a number of examples of the use of the formulas for bevel gear calculations. While it is not necessary in practice to have the dimensions accurate within 0.0001 inch, it is well to carry out the calculations to four decimal places. This permits accurate checking of the results by Formulas (3) and (21).

Shafts at Right Angles. — Let it be required to make the necessary calculations for a pair of bevel gears in which the shafts are at right angles; diametral pitch = 3, number of teeth in gear = 60, number of teeth in pinion = 15, and width of face = 4 inches.

$$\tan \alpha_p = 15 \div 60 = 0.25000 = \tan 14^\circ\ 2' \tag{1}$$

$$\tan \alpha_g = 60 \div 15 = 4.00000 = \tan 75^\circ\ 58' \tag{2}$$

$$\gamma = 14^\circ\ 2' + 75^\circ\ 58' = 90^\circ \tag{3}$$

$$D_p = 15 \div 3 = 5.000'' \tag{4}$$

$$S = 1 \div 3 = 0.3333'' \tag{5}$$

$$S + A = \frac{1.157}{3} = 0.3856'' \tag{6}$$

$$W = \frac{2.157}{3} = 0.7190'' \tag{7}$$

$$T = \frac{1.571}{3} = 0.5236'' \tag{8}$$

$$C = \frac{5}{2 \times 0.24249} = 10.3097'' \tag{9}$$

$$s = 0.3333 \times \frac{6.31}{10.31} = 0.2040'' \tag{10}$$

$$t = 0.5236 \times \frac{6.31}{10.31} = 0.3204'' \tag{11}$$

$$\tan \theta = \frac{0.3333}{10.3097} = 0.03233 = \tan 1^\circ\ 51' \tag{12}$$

$$\tan \phi = \frac{0.3856}{10.3097} = 0.03740 = \tan 2^\circ\ 9' \tag{13}$$

$$\delta = 90^\circ - (14^\circ\ 2' + 1^\circ\ 51') = 74^\circ\ 7' \tag{14}$$

$$\zeta = 14^\circ\ 2' - 2^\circ\ 9' = 11^\circ\ 53' \tag{15}$$

$$K = 0.3333 \times 0.97015 = 0.3234'' \tag{16}$$

$$O = 5.000 + 2 \times 0.3234 = 5.6468'' \tag{17}$$

$$J = \frac{5.6468}{2} \times 3.51441 = 9.9225'' \tag{18}$$

$$j = 9.9225 \times \frac{6.31}{10.31} = 6.0726'' \tag{19}$$

$$N' = \frac{15}{0.97015} = 15.4 \tag{20}$$

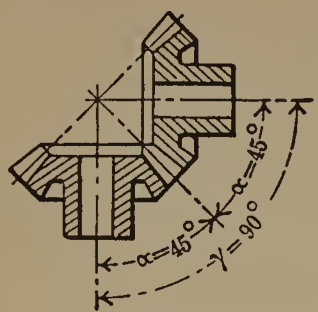
$$5.6468'' = \frac{20.6194 \times 0.27368}{0.99948} = 5.6461'' \tag{21}$$

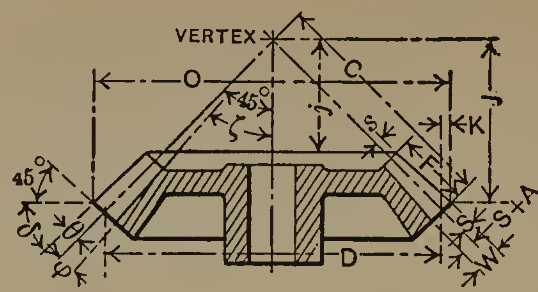
This gives all the data required for the pinion. Rules (5) to (13), inclusive, apply equally to the gear and the pinion, so that only calculations by Rules and Formulas (4) and (14) to (21) need be made for the gear, although it is well to calculate Formula (9) a second time as a check for the same calculation for the pinion.

$$D = \frac{60}{3} = 20.000'' \tag{4}$$

$$C = \frac{20}{2 \times 0.97015} = 10.3077'' \tag{9}$$

Rules and Formulas for Calculating Miter Bevel Gearing





Use Rules and Formulas Nos. 22, 4–8, 23, 10–13, 24–26, 17–19, 27 and 21 in the order given. All dimensions thus obtained are the same for both gears of a pair.

No.	To Find	Rule	Formula
22	Pitch Cone Angle.	Pitch cone angle equals 45 degrees.	$\alpha = 45°$
23	Pitch Cone Radius.	Multiply the pitch diameter by 0.707.	$C = 0.707\ D$
24	Face*Angle.	Subtract the addendum angle from 45°.	$\delta = 45° - \theta$
25	Cutting Angle.*	Subtract the dedendum angle from 45°.	$\zeta = 45° - \phi$
26	Angular Addendum.	Multiply the addendum by 0.707.	$K = 0.707\ S$
27	Number of Teeth for which to Select Cutter.	Multiply the number of teeth by 1.41.	$N' = 1.41\ N$

* See paragraph "Formulas for Bevel Gear Calculations."

$$\delta = 90 - (75°\ 58' + 1°\ 51') = 12°\ 11' \tag{14}$$

$$\zeta = 75°\ 58' - 2°\ 9' = 73°\ 49' \tag{15}$$

$$K = 0.3333 \times 0.24249 = 0.0808'' \tag{16}$$

$$O = 20 + 2 \times 0.0808 = 20.1616'' \tag{17}$$

$$J = \frac{20.1616}{2} \times 0.2159 = 2.1764'' \tag{18}$$

$$j = 2.1764 \times \frac{6.31}{10.31} = 1.3320'' \tag{19}$$

$$N' = \frac{60}{0.24249} = 247 \tag{20}$$

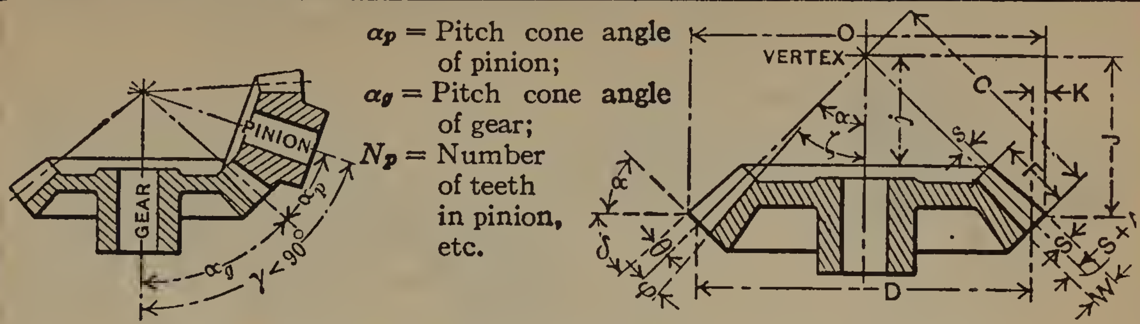
$$20.1616'' \cong \frac{20.6154 \times 0.97748}{0.99948} = 20.1615'' \tag{21}$$

This gives the calculations necessary for this pair of gears.

Acute Angle Bevel Gearing.— Let it next be required to calculate the dimensions of a pair of bevel gears the center angle of which is 75 degrees, the number of teeth in the pinion 15, the number of teeth in the gear 60, the diametral pitch 3, and the width of face 4 inches. Following the directions given in the tables of rules and formulas for bevel gear calculations:

$$\tan \alpha_p = \frac{0.96593}{\frac{60}{15} + 0.25882} = 0.22681 = \tan 12°\ 47' \tag{28}$$

Rules and Formulas for Calculating Bevel Gears with Shafts at an Acute Angle



α_p = Pitch cone angle of pinion; α_g = Pitch cone angle of gear; N_p = Number of teeth in pinion, etc.

Use Rules and Formulas Nos. 28–30, and 4–21 in the order given.

No.	To Find	Rule	Formula
28	Pitch Cone Angle (or Edge Angle) of Pinion.	Divide the sine of the center angle by the sum of the cosine of the center angle and the quotient of number of teeth in the gear divided by the number of teeth in the pinion; this gives the tangent.	$\tan \alpha_p = \dfrac{\sin y}{\dfrac{N_g}{N_p} + \cos y}$
29	Pitch Cone Angle (or Edge Angle) of Gear.	Divide the sine of the center angle by the sum of the cosine of the center angle and the quotient of the number of teeth in the pinion divided by the number of teeth in the gear; this gives the tangent.	$\tan \alpha_g = \dfrac{\sin y}{\dfrac{N_p}{N_g} + \cos y}$
30	Proof of Calculations for Pitch Cone Angles.	The sum of the pitch cone angles of the pinion and gear equals the center angle.	$\alpha_p + \alpha_g = y$

$$\tan \alpha_g = \frac{0.96593}{\frac{15}{60} + 0.25882} = 1.89837 = \tan 62° \, 13' \qquad (29)$$

$$\gamma = 12° \, 47' + 62° \, 13' = 75° \qquad (30)$$

Formulas (4) to (8) as in first example; also, $C = 11.2989''$, $s = 0.2154''$, $t = 0.3382''$, $\theta = 1° \, 41'$, $\phi = 1° \, 57'$, $\delta = 75° \, 32'$, $\zeta = 10° \, 50'$, $K = 0.3251''$, $O = 5.6502''$, $J = 10.9501''$, $j = 7.0748''$, and $N' = 15.3$, also,

$$5.6502'' \cong \frac{22.598 \times 0.24982}{0.99957} = 5.6483'' \qquad (21)$$

For the gear, the additional calculations give: $C = 11.303''$, $\delta = 26° \, 6'$, $\zeta = 60° \, 16'$, $K = 0.1553''$, $O = 20.3106''$, $J = 4.9748''$, $j = 3.2142''$, $N' = 129$.

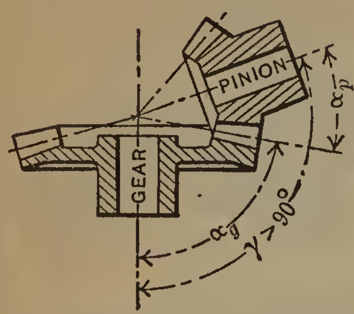
$$20.3106'' \cong \frac{22.606 \times 0.89803}{0.99957} = 20.3096'' \qquad (21)$$

The above calculations are not all given in full, as most of them are merely duplications of formulas previously used.

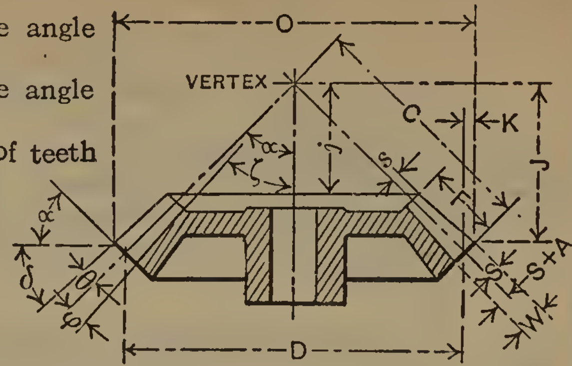
Obtuse Angle Bevel Gearing. — Let it be required to calculate the dimensions of the same set of gears with a center angle of 100 degrees. This being an example of obtuse angle gearing, apply Formula (31) as follows:

$$\tan \alpha_p = \frac{0.98481}{\frac{60}{15} - 0.17365} = 0.25738 = \tan 14° \, 26' \qquad \mathbf{(31)}$$

Rules and Formulas for Calculating Bevel Gears with Shafts at an Obtuse Angle



α_p = Pitch cone angle of pinion;
α_g = Pitch cone angle of gear;
N_p = Number of teeth in pinion, etc.



Use Rules and Formulas Nos. 31 and 32 as directed below.

No.	To Find	Rule	Formula
31	Pitch Cone Angle (or Edge Angle) of Pinion.	Divide the sine of 180 degrees minus the center angle by the difference between the quotient of the number of teeth in the gear divided by the number of teeth in the pinion and the cosine of 180 degrees minus the center angle; this gives the tangent.	$\tan \alpha_p = \dfrac{\sin (180^\circ - \gamma)}{\dfrac{N_g}{N_p} - \cos (180^\circ - \gamma)}$
32	Whether Gear is a Regular Bevel Gear, a Crown Gear, or an Internal Bevel Gear.	Add 90 degrees to the pitch cone angle of the pinion. If the sum is greater than the center angle use Rules and Formulas Nos. 33, 30 and 4–21 in the order given. If the sum equals the center angle see rules and formulas for crown gear. If the sum is less than the center angle see rules and formulas for internal bevel gear.	
33	Pitch Cone Angle (or Edge Angle) of Gear.	Divide the sine of 180 degrees minus the center angle by the difference between the quotient of the number of teeth in the pinion divided by the number of teeth in the gear and the cosine of 180 degrees minus the center angle; this gives the tangent.	$\tan \alpha_g = \dfrac{\sin (180^\circ - \gamma)}{\dfrac{N_p}{N_g} - \cos (180^\circ - \gamma)}$

and thus discover that it is an example of regular obtuse angle gearing, since

$$14^\circ\ 26' + 90^\circ = 104^\circ\ 26' > 100^\circ \tag{32}$$

The remaining calculations for the angles are as follows:

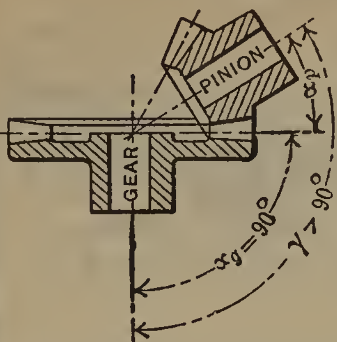
$$\tan \alpha = \frac{0.98481}{\frac{15}{60} - 0.17365} = 12.8986 = \tan 85^\circ\ 34' \tag{33}$$

$$\gamma = 14^\circ\ 26' + 85^\circ\ 34' = 100^\circ \tag{30}$$

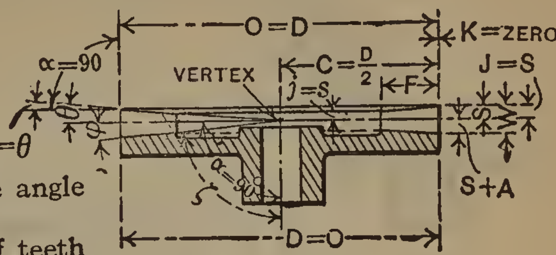
and the calculations for the other dimensions as per the table.

Crown Gear. — Suppose it is required to make a crown gear and a pinion for the same number of teeth, pitch and face as in the previous examples. What are

Rules and Formulas for Calculating Crown Gears



α_p = Pitch cone angle of pinion;
N_p = Number of teeth in pinion;
N_g = Number of teeth in gear, etc.



Use Rules Nos. 31 and 4–21 in the order given, for the pinion; use Rules Nos. 30, 4–8, 36, 10–13, 37, 15 and 38 in the order given for the crown gear; if dimensions for crown gear are known, to find center angle and dimensions of pinion, use Rules and Formulas Nos. 34, 35 and 4–21 in the order given.

No.	To Find	Rule	Formula
34	Pitch Cone Angle (or Edge Angle) of Pinion.	Divide the number of teeth in the pinion by the number of teeth in the gear, to get the sine.	$\sin\alpha_p = \frac{N_p}{N_g}$
35	Center Angle.	Add 90 degrees to the pitch cone angle of the pinion.	$\gamma = 90^\circ + \alpha_p$
36	Pitch Cone Radius.	Divide the pitch diameter by 2.	$C = \frac{D}{2}$
37	Face Angle of Gear.	The face cone angle of the gear equals the addendum angle.	$\delta_g = \theta$
38	Number of Teeth for which to Select Cutter.	The teeth are equivalent in form to rack teeth.	$N_g' =$ infinity

the additional calculations necessary? Following the proper formulas in the order given:

$$\sin\alpha_p = \frac{15}{60} = 0.25000 = \sin 14^\circ\ 29' \tag{34}$$

$$\gamma = 90^\circ + 14^\circ\ 29' = 104^\circ\ 29' \tag{35}$$

The other calculations are similar to those already given.

Internal Bevel Gear. — Let it be required to design a pair of bevel gears of the same number of teeth, pitch and face, in which the center angle is 115 degrees. This being an example of obtuse angle gearing, use Formula (31).

$$\tan\alpha_p = \frac{0.90631}{\frac{60}{15} - 0.42262} = 0.25334 = \tan 14^\circ\ 13' \tag{31}$$

Then, according to Rule (32):

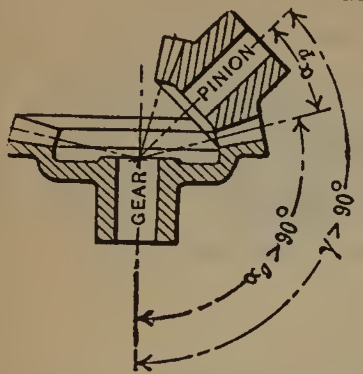
$$14^\circ\ 13' + 90^\circ = 104^\circ\ 13' < 115^\circ \tag{32}$$

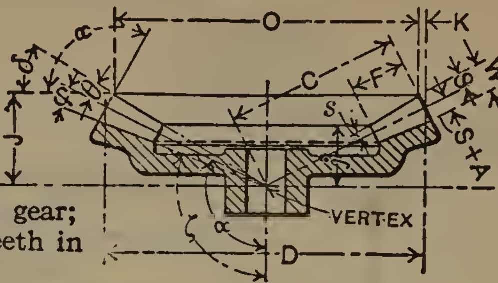
showing that the gear is an internal bevel gear. Applying the rules and formulas for internal bevel gearing:

$$\tan\alpha_a = \frac{0.90631}{0.42262 - \frac{15}{60}} = 5.25032 = \tan 79^\circ\ 13'$$

$$180^\circ - 79^\circ\ 13' = 100^\circ\ 47' \tag{39}$$

Rules and Formulas for Calculating Internal Bevel Gears





δ_g = Face angle of gear;
N_p = Number of teeth in pinion;
N_g = Number of teeth in gear, etc.

Use Rules and Formulas Nos. 31 and 4–21 inclusive for the pinion; use Rules and Formulas Nos. 39, 30, 40, 41, 15, 42, 43, 18, 19, 44 and 21 in the order given for the gear.

No.	To Find	Rule	Formula
39	Pitch Cone Angle (or Edge Angle) of Gear.	Divide the sine of 180 degrees minus the center angle by the difference between the cosine of 180 degrees minus the center angle and the quotient of the number of teeth in the pinion divided by the number of teeth in the gear; subtract the angle whose tangent is thus found from 180 degrees.	$\tan \alpha_a = \dfrac{\sin(180 - \gamma)}{\cos(180 - \gamma) - \dfrac{N_p}{N_g}}$ $\alpha_g = 180 - \alpha_a$
40	Pitch Cone Radius.	Divide the pitch diameter by twice the sine of 180 degrees minus the pitch cone angle.	$C = \dfrac{D_g}{2 \sin(180 - \alpha_g)}$
41	Face Angle of Gear.	Subtract 90 degrees from the sum of the pitch cone angle and the addendum angle.	$\delta_g = \alpha_g + \theta - 90°$
42	Angular Addendum of Gear.	Multiply the addendum by the cosine of 180 degrees minus the pitch cone angle.	$K_g = S \times \cos(180 - \alpha_g)$
43	Outside (or Edge) Diameter of Gear.	Subtract twice the angular addendum from the pitch diameter.	$O_g = D_g - 2K_g$
44	Number of Teeth for which to Select Cutter.	Divide the number of teeth by the cosine of 180 degrees minus the pitch cone angle.	$N_g' = \dfrac{N_g}{\cos(180 - \alpha_g)}$

$$\gamma = 100° \, 47' + 14° \, 13' = 115° \qquad (30)$$

$$C = \frac{20}{2 \times 0.98234} = 10.1797'' \qquad (40)$$

$$\delta = 100° \, 47' + 1° \, 53' - 90° = 12° \, 40' \qquad (41)$$

$$\zeta = 98° \, 37', \text{ and } K = 0.0624''$$

$$O = 20 - 2 \times 0.0624 = 19.8752'' \qquad (43)$$

$$N' = \frac{60}{0.1871} = 320 \text{ (internal)} \qquad (44)$$

The calculations for the pinion and the other calculations for the gear are similar to those already given.

Forms of Bevel Gear Teeth. — Five systems of tooth outlines are used for bevel gearing. They are the cycloid, the standard 14½-degree involute, the 20-degree involute, and the 15- and 20-degree octoid. The cycloidal form of tooth is obsolete for cut bevel gears, and is also rarely met with nowadays for cast gears. It requires very careful workmanship, and is difficult or impossible to generate. Most bevel gears are, therefore, made on the involute system, with either the standard 14½-degree or the 20-degree pressure angle. The 20-degree tooth is broader at the base and stronger in form than the 14½-degree tooth, but most bevel gears that are milled with form cutters are made to the 14½-degree standard. Planed gears made by the templet or generating processes are nowadays often made to the 20-degree pressure angle.

When planing a pair of bevel gears on the Bilgram, Gleason or other similar generating machines, a form of tooth named the "octoid" is used. In generating machines the teeth of the gears are shaped by a tool which represents the side of the tooth of an imaginary crown gear. The cutting edge of the tool is a straight line, since the imaginary crown gear has teeth whose sides are plane surfaces. It can be shown that the teeth of a true involute crown gear have sides which are very slightly curved. The minute difference between the tooth shapes produced by a plane crown tooth and a slightly curved crown tooth is the minute difference between the octoid and involute forms. Both give theoretically correct action.

Tables for Determining the Outside Diameter of Bevel Gears. — These tables are used for finding the outside diameter of bevel gears when the pitch diameter is known, and apply only to bevel gears with axes at right angles. The figures given in the table (in the column giving the number of teeth in the gear and opposite the number of teeth in the pinion) are for 1 diametral pitch; they are, therefore, to be divided by the diametral pitch of the gears, and the quotient thus obtained is added to the pitch diameter. For each combination of teeth, two figures are given. The upper value is for the gear and the lower for the pinion.

Example. — Find the outside diameter of a pair of bevel gears, 10 diametral pitch, with 35 and 23 teeth.

In the tables the diameter increments are found to be 1.10 for the gear and 1.67 for the pinion, for 1 diametral pitch. For 10 diametral pitch, then, $1.10 \div 10 = 0.110$, and $1.67 \div 10 = 0.167$. The pitch diameter of the gear is 3.5 inches; thus, $3.5 + 0.110 = 3.610$ inches is the outside diameter of the gear. The pitch diameter of the pinion is 2.3 inches; hence, $2.3 + 0.167 = 2.467$ inches is the outside diameter of the pinion.

The table "Diameter Increments for Bevel Gears" can be used in cases where the required number of teeth is not given in the tables just referred to. The object of the table is the same — that of obtaining the outside diameter when the pitch diameter is known. In these tables the column headed "Ratio" gives the ratio of the number of teeth in a pair of gears, and the two columns headed "Gear" and "Pinion" give the amount to add to the pitch diameter to obtain the outside diameter for 1 diametral pitch. Thus, to find the diameter increments, first divide the number of teeth in the gear by the number of teeth in the pinion, and find this ratio in the table. Then divide the values given in the table opposite this ratio by the given pitch. The table is applicable to bevel gears with axes at right angles only.

Example. — Find the outside diameter of a pair of bevel gears, 75 and 20 teeth, 6 diametral pitch.

Dividing the number of teeth in the gear by the number of teeth in the pinion gives a ratio of 3.75. From the table the diameter increment is then found to be 0.515 for the gear, and 1.933 for the pinion. Dividing each by 6 gives 0.086 and 0.322. The pitch diameter of the gear is 12.5 inches and of the pinion 3.333 inches. Adding the diameter increments just found gives 12.586 inches for the outside diameter of the gear, and 3.655 inches for the outside diameter of the pinion.

Diameter Increments for Bevel Gears

Of the two values given, the upper is for the gear, the lower for the pinion.

Edge or Pitch Cone Angles, Face Angles and Cutting Angles of Bevel Gears. — These tables have been computed by the Brown & Sharpe Mfg. Co. for convenience in calculating the data for bevel gears with axes at right angles. They do not apply to bevel gears with axes at any other angle. To use the tables, the number of teeth in the gear and pinion must be known. Locate the number of teeth in the gear on the horizontal line at the top of the table and the number of teeth in the pinion in the vertical column on the left-hand side. At the intersection of the lines or columns for these numbers of teeth, two angles are given. The angle applying to the gear is always placed above the angle applying to the pinion.

The tables "Face Angles of Bevel Gears" are arranged in the same manner as the tables for "Edge or Pitch Cone Angles." Of the two angles that are given for each combination of number of teeth, the upper is for the gear, and the lower for the pinion. The cutting angle for a gear or pinion, when cut by rotary milling cutters, is equal to the angle of face of its mate.

As an example of the use of the tables, find the cutting angles for a pair of bevel gears with 15 and 60 teeth. From the table on page 673, these angles are found to be 12 deg. 11 min., and 74 deg. 7 min., if the gears are cut with rotary milling cutters.

Edge or Pitch Cone Angles of Bevel Gears

Of the two angles given, the upper is for the gear, the lower for the pinion.

Materials Used for Making Bevel Gears. — Cast iron is used for the largest work, and for smaller work which is not to be subjected to heavy duty. In cases where great working stress or a sudden shock is liable to come on the teeth, steel is ordinarily used. Such gears are made from bar stock for the smallest work, from drop forgings for intermediate sizes made on a manufacturing basis and from steel castings for heavy work. The softer grades of steel are not suitable for high-speed service, as this material abrades more rapidly than cast iron. This objection does not apply to hardened steel, such as is used in automobile transmission gears.

It is quite common to make the gear and pinion of different materials. This is advantageous from the standpoint of both efficiency and durability. Cast iron and steel, and steel and bronze are common combinations. In general, the pinion should be made of the stronger material, since it is of weak form; and it should be made of the more durable material, as it revolves more rapidly and each tooth comes into working contact more times per minute than do those of the larger mating gear. In a steel and cast iron combination, then, the pinion should be of steel, while the gear is of cast iron.

Rawhide and fiber are quite largely used for pinion blanks in cases where it is desired to run gearing at a very high speed and with as little noise as possible. Fiber, has the merit of convenience and comparative inexpensiveness, as it may be purchased in a variety of sizes of bars, rods, tubes, etc., ready to be worked up into pinion blanks; but it is not so strong as rawhide, and is difficult to machine owing to its gritty composition. It is satisfactory for light duty at high speed.

Face Angles of Bevel Gears

(Table is also used for finding *cutting angles* of gears cut with rotary milling cutters. See explanatory paragraph, page 666.)

Of the two angles given, the upper is for the gear, the lower for the pinion.

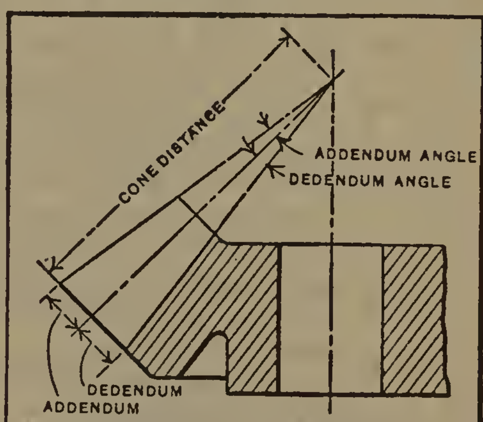
Dedendum Angles for Different Addendum Angles. — When the shafts of bevel gears are not at right angles or when the depth of the tooth is greater or smaller than the standard depth for the thickness of tooth used, the table "Dedendum Angles for Different Addendum Angles" may be employed. The addendum angle is first calculated from the formula:

Addendum ÷ cone distance
= tangent of addendum angle.



Then the dedendum angle may be found directly from the table. When the table is used for teeth that are not of standard depth, the *ratio* of the dedendum to the addendum must still remain the same as for standard involute teeth.

As an example of the use of the table, find the dedendum angle for an addendum angle of 3 degrees 43 minutes. At the intersection of the vertical column under 3 degrees and the horizontal line opposite 43 minutes, the answer, 4 degrees 18 minutes, is found. This difference between addendum and dedendum angles does not apply to gears cut by rotary cutters (see page 652).

Dedendum Angles for Different Addendum Angles

For bevel gears with axes at right angles.
Number of cutter for gear given first, followed by number for pinion.

General Considerations Relating to Design of Bevel Gears. — The performance of the most carefully designed and made bevel gears depends to a considerable extent on the design of the machine in which they are used. When the shafts on which a pair of bevel gears are mounted are poorly supported or poorly fitted in their bearings, the pressure of the driving gear on the driven causes it to climb upon the latter, throwing the shafts out of alignment. This in turn causes the teeth to bear with a greater pressure at one end of the face (usually at the outer end) than at the other, thus making the tooth more liable to break than is the case when the pressure is more evenly distributed. It is important, therefore, to provide rigid shafts and bearings and careful workmanship for bevel gearing.

Proportions of Bevel Gears. — Various forms may be given to the blanks or wheels on which bevel gear teeth are cut, depending on the size, material, service, etc., to be provided for. The pinion type of blank is mostly used for gears of a small number of teeth and small pitch cone angle. When the diameter of the bore comes too near to the bottoms of the teeth at the small end, it is customary to omit the usual recess in the front face. For gears of a larger number of teeth, the web type is appropriate. This does not require to be finished all over, as the sides of the web, the outside of the hub, and the under side of the rim may be rough.

A gear suitable for very heavy work should have the web reinforced by ribs. The web may be cut out so that the rim is supported by T-shaped arms. This makes a very stiff wheel and at the same time a very light one, in proportion to its strength.

The question of alignment of the shafts should be considered in deciding upon the width of face of the gear. Making the width of the face more than one-third of the pitch cone radius adds practically nothing to the strength of the gear, since the added portion is progressively weaker as the tooth is lengthened. In addition to this, there is the danger that through springing of the shafts or poor workmanship, the load will be thrown onto the weak end of the tooth, thus fracturing it. For this reason it may be laid down as a definite rule that there is nothing to be gained by making the face of the bevel gear more than one-third of the pitch cone radius.

The Brown & Sharpe Mfg. Co., in one of its publications, gives a rule for the maximum width of face allowable for a given pitch. The width of face should not exceed 2½ times the circular pitch, or 8 divided by the diametral pitch. This rule is rational, since the danger to the teeth from the misalignment of the shafts increases both with the width of face and with the decrease of the size of the tooth, so that both of these should be reckoned with. In designing gearing it is well to check the width of face from the rule relating to the pitch cone radius and that relating to the pitch as well, to see that it does not exceed the maximum allowed by either.

Table for Selecting Cutters for Bevel Gears. — This table gives the number of cutter to use for various numbers of teeth in the gear and pinion. It applies to bevel gears with axes at right angles only. The number of the cutter for the gear is given first, followed by the number for the pinion.

Example. — Required the cutters for a pair of bevel gears where the gear has 24 teeth and the pinion, 12 teeth. The table shows that the numbers of the cutters to be used are Nos. 3 and 8, No. 3 being for the gear, and No. 8 for the pinion.

For 14½-degree involute teeth, the standard cutter series furnished by the makers of formed gear cutters is commonly used. There are 8 cutters in the series, to cover the full range from the 12-tooth pinion to a crown gear. The standard bevel gear cutter is made thinner than the standard spur gear cutter, as it must pass through the narrow tooth space at the inner end of the face. As usually kept in stock, these cutters are thin enough for bevel gears in which the width of face is not more than one-third the pitch cone radius.

Offset of Cutter for Milling Bevel Gears. — When milling bevel gears with a rotary formed cutter, it is necessary to take two cuts through each tooth space with the gear blank slightly off center, first on one side and then on the other, to obtain a tooth of approximately the correct form. The gear blank is also rotated proportionately to obtain the proper tooth thickness at the large and small ends. The amount that the gear blank or cutter should be offset from the central position can be determined quite accurately by the use of the table "Factors for Obtaining Offset for Cutting Bevel Gears," in conjunction with the following rule: Find the factor in the table corresponding to the number of cutter used and to the ratio of the pitch cone radius to the face width; then divide this factor by the diametral pitch and subtract the result from half the thickness of the cutter at the pitch line.

Factors for Obtaining Offset for Cutting Bevel Gears

No. of Cutter	Ratio of Pitch Cone Radius to Width of Face $\left(\frac{C}{F}\right)$

Note. — For obtaining offset by above table, use formula:

$$\text{Offset} = \frac{T}{2} - \frac{\text{factor from table}}{P}$$

P = diametral pitch of gear to be cut;

T = thickness of cutter used, measured at pitch line.

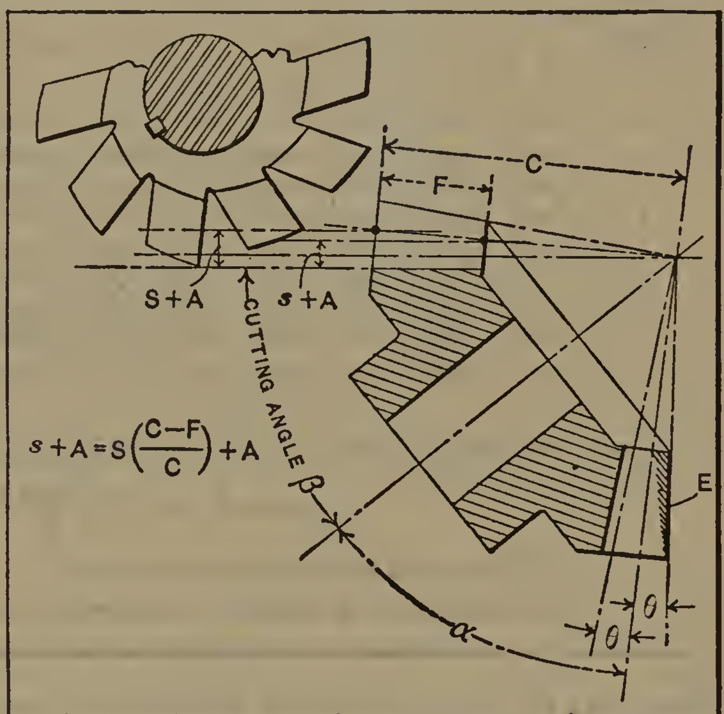
Expressing this rule as a formula, in which O = amount of offset; T = thickness of cutter at pitch line; P = diametral pitch of gear; F = factor from table, we have

$$O = \frac{T}{2} - \frac{F}{P}$$

To illustrate, what would be the amount of offset for a bevel gear having 24 teeth, 6 pitch, 30-degree pitch cone angle and 1¼ inch face or tooth length? In order to obtain a factor from the table, the ratio of the pitch cone radius to the face width must be determined. The pitch cone radius equals the pitch diameter divided by twice the sine of the pitch cone angle $= \frac{4}{2 \times 0.5} = 4$ inches. As the face width is 1.25, the ratio is $\frac{4}{1.25} = \frac{3.2}{1}$ or about 3¼. The factor in the table for this ratio is 0.280 with a No. 4 cutter, which would be the cutter number for this particular gear. The thickness of the cutter at the pitch line is measured by using a vernier gear tooth caliper. The depth $S + A$ (see illustration; S = addendum; A = clearance) at which to take the measurement equals 1.157 divided by the diametral pitch; thus, $1.157 \div 6 = 0.1928$ inch. The cutter thickness at this depth will vary with different cutters and even with the same cutter as it is ground away, because formed bevel gear cutters are commonly provided with side relief. Assuming that the thickness is 0.1745 inch, and substituting the values in the formula given, we have:

$$\text{Offset} = \frac{0.1745}{2} - \frac{0.280}{6} = 0.0406.$$

Adjusting the Gear Blank for Milling. — After the offset is determined, the blank is adjusted laterally this amount, and the tooth spaces are milled around the blank. After having milled one side of each tooth to the proper dimensions, the blank is set over in the opposite direction the same amount from a position central with the cutter, and is rotated to line up the cutter with a tooth space at the small end. A trial cut is then taken, which will leave the tooth being milled a little too thick, provided the cutter is thin enough — as it should be — to pass through the small end of the tooth space of the finished gear. This trial tooth is made the proper thickness by rotating the blank toward the cutter. To test the amount of offset measure the tooth thickness (with a vernier caliper) at the large and small ends. The caliper should be set so that the addendum at the small end is in proper proportion to the addendum at the large end; that is, in the ratio, $\frac{C-F}{C}$ (see illustration). In taking these measurements, if the thicknesses at both ends (which should be in this same ratio) are too great, rotate the tooth toward the cutter and take trial cuts until the proper thickness at either the large or small end is obtained. If the large end of the tooth is the right thickness and the small end too thick, the blank was offset too much; inversely, if the small end is correct and the large end too thick, the blank was not set enough off center, and, in either case, its position should be changed accordingly. The formula and table previously referred to will enable a properly turned blank to be set accurate enough for general work. The dividing head should be set to the cutting angle β (see illustration), which is found by subtracting the addendum angle θ from the pitch cone angle α. After cutting a bevel gear by the method described, the sides of the teeth at the small end should be filed as indicated by the shade lines at E; that is, by filing off a triangular area from the point of the tooth at the large end to the point at the small end, thence down to the pitch line and back diagonally to a point at the large end.



Long Addendum Bevel Gears. — In order to obtain more quietly running gears and greater strength and durability, especially in automobile rear axle bevel gear transmissions, the common practice has been to lengthen the addendum of the pinion tooth and shorten the addendum of the gear tooth a corresponding amount, the whole depth of the tooth remaining the same as for standard involute teeth. With this system, a smaller number of pinion teeth can be used than would be possible with teeth of standard proportions. The addendum of the pinion tooth equals 0.7 of the working depth and the gear tooth addendum equals 0.3 of the working depth both for 14½- and 20-degree pressure angles. (This Gleason 0.7 and 0.3 standard has been supplemented by another system which is briefly described in the following paragraph.) The circular thickness of the tooth at the pitch line, using these dimensions, is 0.566 times the circular pitch for the pinion, and 0.434 times the circular pitch for the gear, for the 14½-degree pressure angle. For the 20-degree pressure angle, the circular thickness is 0.5927 times the circular pitch for the pinion, and 0.4073 times the circular pitch for the gear. For gears of this type the 20-degree pressure angle is extensively used. The long addendum pinion must always be the driver.

Gleason Works System of Bevel Gears. — The system of bevel gears introduced by the Gleason Works, Rochester, N. Y., is designed to give the quietest form of tooth consistent with strength and wearing qualities. With this system the gear addendum is decreased and the pinion addendum is increased as the ratios of the numbers of teeth in the gear and pinion become greater. The basis of the system is in using the lowest pressure angle that can be employed without sacrificing strength by introducing excessive under-cut. The use of a low pressure angle in preference to a higher one does not reduce the effective strength to the extent ordinarily supposed, because the stronger tooth section of the higher pressure angle is offset by the greater arc of action with the lower angle. The Gleason system has three pressure angles of 14½, 17½, and 20 degrees for all straight-tooth bevel gears having ten or more teeth in the pinion, and one angle of 14½ degrees for spiral bevel gears, except in a few special cases. This system is applicable to any pair of generated spiral- or straight-tooth bevel gears operating at right angles, where the pinion is the driver and, in the case of straight tooth gearing, has ten or more teeth; spiral bevel gears having less than ten teeth are included in the system.

Corrected Pitch Depth for Bevel Gears. — In order to measure the theoretically correct thicknesses of a bevel gear tooth, the "corrected pitch depth" or "corrected addendum" and the chordal thickness must be determined. The chordal thickness is the same as for a spur gear having the same number of teeth and pitch (see formula on page 638). The corrected pitch depth for a bevel gear is obtained by the following formula in which H = corrected pitch depth; S = addendum; R = pitch radius; α = pitch cone angle; b = angle subtended by lines from the apex of the back cone, which intersect one side and the center of the tooth respectively, at the pitch line.

$$H = S + \frac{R}{\cos\alpha}(1 - \cos b)$$

The sine of angle b is found by the following formula in which N = the number of teeth:

$$\text{Sin}\, b = \sin\left(\frac{90}{N}\right)\cos\alpha$$

Recommended Practice for Bevel Gearing. — The American Gear Manufacturers' Association adopted as recommended practice the following rules:

The maximum length of face of bevel gears should not be over one-third of the cone distance for gears up to 3 inches pitch diameter and not over one-quarter of the cone distance for gears from 3 to 20 inches pitch diameter, assuming that the pitch in every case will be in proper proportion to the size of the gears. A safe rule is to make the face from 1½ to 2½ times the circular pitch.

The minimum length of bearing along the face is to be at least one-half the length of the face when the gears are held in correct alignment. Gear users should test the strength of the gear housings as follows: Block the driven gear shaft and then apply a lever to the shaft of the driving gear and measure the displacement of both gears when a dead load is applied through the lever. This measurement can be made by inserting feelers or shims on the driving side of both ends of the teeth before and after the load is applied.

Bevel gears with generated involute teeth of standard addendum, having a pressure angle of 14½ degrees, may be used according to the following rule:

Ratio	Number of Teeth
1 to 1	14 and over
1½ to 1	18 and over
2 to 1	19 and over
3 to 1 and over	21 and over

The rules as given apply mainly to gears up to 20 inches pitch diameter and to average machine design as distinguished from gears for automobiles.

Strength of Bevel Gears. — The method for calculating the strength of bevel gearing is based on the Lewis formula for the strength of gear teeth, and is practically the same as that used for spur gears. The accompanying tables of "Rules and Formulas for the Strength of Bevel Gears," and "Factors for Calculating the Strength of Bevel Gears," in combination with the table "Working Stresses used in the Lewis Formula for the Strength of Gear Teeth," in the section on spur gearing, give all the necessary data for calculating the strength of bevel gears. The formulas and factors given are based on the use of the diametral pitch of the gears, and constants Y given in the factor table are figured for diametral pitch. If the circular pitch is given, it should be transformed into diametral pitch by dividing 3.1416 by the circular pitch. By means of the Formulas (1) to (4), the horsepower which can be transmitted by a gear of given pitch diameter and diametral pitch, running at a given number of revolutions per minute, can be found. The formulas should be used in the order given. The allowable static unit stress S_s is found from the first line (velocity = 0) in the table of "Working Stresses used in the Lewis Formula for the Strength of Gear Teeth" given in the section on spur gearing. The allowable working stress S at any velocity may also be found directly from the table.

As an example, find the horsepower which can be safely transmitted by a bevel gear having 15 inch pitch diameter, 60-degree pitch cone angle, 4 diametral pitch, making 100 revolutions per minute and having a width of face of 1½ inch. The teeth are cut according to the 14½-degree involute system. The gear is made of steel and the allowable static unit stress for the material, as found from the table of working stresses in the section on spur gearing, may be assumed to be 15,000 pounds per square inch. First insert the values of the pitch diameter and the revolutions per minute in Formula (1). This gives the velocity in feet per minute at the pitch diameter. Then insert this velocity, as found in Formula (1), together with the allowable static unit stress, in Formula (2), thus finding the allowable unit stress at the given velocity. This unit stress is now inserted, together with the width of face, the outline factor Y (found from the factor table to be about 0.373 for $N' = 60 \div \cos 60° = 120$), the factor $\frac{C-F}{C}$ and the diametral pitch, in Formula (3). This will then give the maximum safe tangential load W. Finally, by inserting the value of W just found and the value of V found from Formula (1), in Formula (4), determine the maximum safe horsepower which can be transmitted by the gear.

The factor $\frac{C-F}{C}$ approximately expresses the ratio of the strength of a bevel gear to that of a spur gear of the same pitch and number of teeth. The smaller strength of the bevel gear is due to the fact that the pitch grows finer towards the vertex of the gear. The factor is approximate only, and should not be used for cases where the width of face is more than one-third of the pitch cone radius C;

but since no bevel gears should be made with width F more than one-third of radius C (see illustration with table), the rule is of universal application for good practice.

As an example showing the application of the rules and formulas for the strength of bevel gears, calculate the maximum load at the pitch line which can be safely carried by a pair of bevel gears of 3 diametral pitch, 20-degree involute teeth, the pitch diameter of the pinion being 5 inches, and of the gear, 20 inches. The maximum allowable static stress for the pinion (made of machine steel) is 20,000 pounds,

Rules and Formulas for the Strength of Bevel Gears

D = pitch diameter of gear in inches;
R = revolutions per minute;
V = velocity in ft. per min. at pitch diam.;
S_s = allowable static unit stress for material;
S = allowable unit stress for material at given velocity;
F = width of face;
N' = No. of teeth in equivalent spur gear (see diagram in table, page 641);
Y = outline factor (see table, page 641);
P = diametral pitch (if circular pitch is given, divide 3.1416 by circular pitch to obtain diametral pitch);
C = pitch cone radius;
W = maximum safe tangential load in pounds at pitch diameter;
H.P. = maximum safe horsepower.

Use Rules and Formulas Nos. 1 to 4 in the order given.

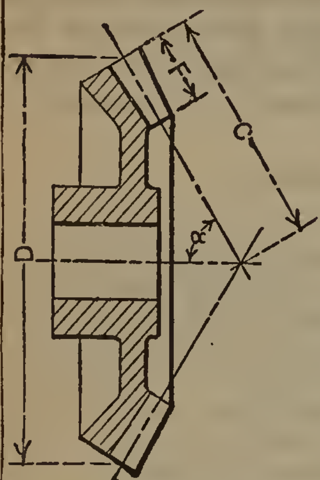
No.	To Find	Rule	Formula
1	Velocity in Feet per Minute at the Pitch Diameter.	Multiply the product of the diameter in inches and the number of revolutions per minute by 0.262.	$V = 0.262\,DR$
2	Allowable Unit Stress at given Velocity.	Multiply the allowable static stress by 600 and divide the result by the velocity in feet per minute plus 600.	$S = S_s \times \frac{600}{600 + V}$
3	Maximum Safe Tangential Load at Pitch Diameter.	Multiply together the allowable stress for the given velocity, the width of face, the tooth outline factor and the difference between the pitch cone radius and the width of face; divide the result by the product of the diametral pitch and the pitch cone radius.	$W = \frac{SFY\,(C-F)}{PC}$
4	Maximum Safe Horsepower.	Multiply the safe load at the pitch line by the velocity in feet per minute, and divide the result by 33,000.	$\text{H.P.} = \frac{WV}{33{,}000}$

and for the gear (made of cast iron), 8000 pounds per square inch. The pinion runs at 300 revolutions per minute. The width of face is 4 inches, and the pitch cone radius, 10.3 inches. Pitch cone angle of pinion, 14 degrees, and of gear 76 degrees. The calculations for the pinion are as follows:

$$N' = \frac{15}{\cos 14^\circ} = 15.5, \text{ approx.}$$

$$V = 0.262 \times 5 \times 300 = 400 \text{ feet per minute (about)} \qquad (1)$$

Factors for Calculating Strength of Bevel Gears



$$N' = \frac{\text{Number of teeth}}{\cos \alpha}$$

Table of Outline Factors (Y) for 14½° and 20° Involute

N'	Outline Factor = Y 14½° Involute (Std.)	Outline Factor = Y 20° Involute	N'	Outline Factor = Y 14½° Involute (Std.)	Outline Factor = Y 20° Involute
12	0.210	0.245	27	0.314	0.349
13	0.220	0.261	30	0.320	0.358
14	0.226	0.276	34	0.327	0.371
15	0.236	0.289	38	0.336	0.383
16	0.242	0.295	43	0.346	0.396
17	0.251	0.302	50	0.352	0.408
18	0.261	0.308	60	0.358	0.421
19	0.273	0.314	75	0.364	0.434
20	0.283	0.320	100	0.371	0.446
21	0.289	0.327	150	0.377	0.459
23	0.295	0.333	300	0.383	0.471
25	0.305	0.339	Rack	0.390	0.484

$$S = 20{,}000 \times \frac{600}{600 + 400} = 12{,}000 \text{ pounds per square inch} \qquad (2)$$

$$W = \frac{12{,}000 \times 4 \times 0.292 \times 6.3}{3 \times 10.3} = 2850 \text{ pounds} \qquad (3)$$

For the gear, the velocity is the same as for the pinion. The necessary calculations are as follows:

$$N' = \frac{60}{\cos 76^\circ} = 250, \text{ approx.}$$

$$S = 8000 \times \frac{600}{600 + 400} = 4800 \text{ pounds per square inch} \qquad (2)$$

$$W = \frac{4800 \times 4 \times 0.467 \times 6.3}{3 \times 10.3} = 1830 \text{ pounds} \qquad (3)$$

The gear is, therefore, the weaker of the two, and thus limits the allowable tooth pressure. The maximum horsepower this gearing will transmit safely is found as follows:

$$\text{H.P.} = \frac{1830 \times 400}{33{,}000} = 22, \text{ approx.} \qquad (4)$$

Durability is practically of as much importance as strength in proportioning bevel gears, but unfortunately no data are as yet available for making satisfactory comparisons of durability.

Simplified Formulas for the Strength of Bevel Gears. — In the section on spur gearing, simplified formulas for the strength of these gears were given by means of which the circular pitch to transmit a given horsepower at a given speed could be found. Formulas similar in form to the spur gear formulas are given in the following. These formulas are based on the assumption that the pinion (for which the strength usually is calculated) has 15 teeth. If the number of teeth in the pinion is other than 15, multiply the horsepower, as given in the formulas below, by $(0.027\,N + 0.6)$, in which N = number of teeth. In the formulas:

P' = circular pitch;
H.P. = horsepower to be transmitted;
R.P.M. = revolutions per minute of the pinion;
D = pitch diameter of 15-tooth pinion.

	Stress according to the Lewis Tables	Stress ⅔ of that given in the Lewis Tables
Cast-iron Bevel Gear	$P' = \sqrt[5]{\dfrac{5.0\,\text{H.P.}^2}{\text{R.P.M.}}}$	$\sqrt[5]{\dfrac{11.0\,\text{H.P.}^2}{\text{R.P.M.}}}$
Cast-steel Bevel Gear	$P' = \sqrt[5]{\dfrac{0.8\,\text{H.P.}^2}{\text{R.P.M.}}}$	$\sqrt[5]{\dfrac{1.8\,\text{H.P.}^2}{\text{R.P.M.}}}$

$$D = 4.77\,P'$$

The formula in the column headed "Stress According to the Lewis Tables" is used for ordinary conditions and steady drive. The column headed "Stress Two-thirds of that given in Lewis Tables" should be used for gears subjected to rapidly varying loads or where the drive is often started and stopped.

Spiral Type Bevel Gears. — This type of gearing is similar to ordinary bevel gearing except that the teeth are curved and are at an angle to the pitch cone radius of the gear. The shape of the tooth which is actually produced is not a spiral or curve in one plane, but, when projected on a plane, is close to a true spiral; hence the name "spiral type bevel gear." The tooth curve, if continued, would intersect the cone center of the gear, which distinguishes the spiral type bevel gear from the "skew bevel gear" in which the tooth elements are straight and do not intersect the cone center, if extended. The spiral type bevel gear is adapted for high-ratio drives; 10-, 11-, and 12-tooth pinions are used in ratios up to 6 to 1 with satisfactory results.

Angle of Spiral. — An angle of spiral which gives a lead of about 1¼ to 1½ times the circular pitch within the width of face has given good results and quiet operation. For 5 diametral pitch and coarser, the angle should be about 30 degrees. For finer pitches, the angle should be between 25 and 30 degrees. The angles may be increased somewhat for very long faces and decreased for very short faces. An angle greater than 35 degrees, however, is not recommended in any case, nor should an angle less than 20 degrees be used.

Right- and Left-hand Gears. — Spiral type bevel gears are either right-hand or left-hand according to the direction of the pinion's spiral. For instance, if the pinion is cut with a right-hand, and the mating gear with a left-hand, spiral, the pair is called "right-hand." The direction of spiral of the pinion is named the same as if it were a threaded screw.

Cutting Spiral Type Bevel Gears. — The cutter used on the Gleason spiral-type bevel gear generator is in the form of a face mill, which holds quite a number of blades or cutters which pass through the blank along a curved path. The same cutter is used for both sides of the tooth and for both pinion and gear. The gear and the cutter roll together, giving correctly generated teeth of involute form. The long and short addendum teeth are used for spiral type bevel gears in order to avoid undercutting in the pinion. The pitch depth of the pinion teeth is made

0.7 of the working depth, and the pitch depth of the gear teeth, 0.3 of the working depth. This determines the face angles and outside diameters of the blanks. On the gear blank, the flank depth will be increased, and care must be taken that there is sufficient metal under the teeth. The same values are used for pitch (either diametral or circular), pitch angle, face angle, root angle, pitch diameter, and outside diameter, as for straight-tooth bevel gearing.

Load Capacity and Wear. — The load-carrying capacity of spiral type bevel gears is practically the same as for straight-tooth gears, and there is no greater tooth wear than in a straight-tooth gear. The only feature tending to change the efficiency of the spiral type bevel gear, as compared with straight bevel gears, is the increased end-thrust, and if this is properly taken care of in the bearings, the decrease in efficiency is negligible. On the other hand, the smoothness of the gears tends to increase their efficiency, offsetting any loss due to the thrust.

End Thrust of Spiral Type Bevel Gears. — When mounting spiral bevel gears, the additional end-thrust caused by the spiral tooth must be considered. This end-thrust is the most important in connection with the pinion and should be provided for in both directions. If the transmitted tooth load (torque) is known, the thrust can be determined approximately by multiplying the transmitted tooth load by a factor C obtained from the accompanying table, "Factors for End-thrust Calculations." These constants are average results for ratios between 3 to 1 and 7 to 1.

If E=end-thrust of pinion; H=number of horsepower to be transmitted; D=pitch diameter, in feet; S=speed of pinion in revolutions per minute; C=factor obtained from table; then:

$$E = \frac{H \times 33{,}000 \times C}{\pi \times D \times S}$$

Values of C with a negative sign indicate pull toward the cone center, as in the case of a pinion having a right-hand spiral and revolving clockwise, as seen from the large end; values with a positive sign indicate thrust away from the gear. The value used for transmitted tooth load or torque is to be figured for the full pitch diameter of the pinion, not the mean diameter.

Example. — Assume that 25 horsepower is to be transmitted; the pinion makes 500 revolutions per minute and has 15 teeth of 5 diametral pitch and a 30-degree angle of spiral. Find the thrust for a right-hand spiral forward drive.

The pitch diameter equals $15 \div 5 = 3$ inches or 0.25 feet; factor C for a right-hand spiral forward drive and 30-degree angle, equals 0.56, and the minus sign preceding it in the table indicates that the thrust will be toward the cone center. Therefore:

$$E = \frac{25 \times 33{,}000 \times 0.56}{3.1416 \times 0.25 \times 500} = 1176 \text{ pounds.}$$

Factors for End-thrust Calculations

Direction of Spiral	Angle of Spiral and Factors C			
	20°	25°	30°	35°
Right-hand Spiral — forward	−0.29	−0.44	−0.56	−0.69
Right-hand Spiral — reverse	+0.41	+0.59	+0.72	+0.85
Left-hand Spiral — forward	+0.41	+0.59	+0.72	+0.85
Left-hand Spiral — reverse	−0.29	−0.44	−0.56	−0.69

Advantages of Spiral Type Bevel Gears. — Spiral type bevel gears are quiet when running, as the engagement is gradual. The teeth, instead of striking a full-line contact at once, roll on each other with an action which suggests the smoothness of a worm and worm-wheel; nevertheless, the action is purely a rolling action, as in the case of straight-tooth gears. Another point of advantage is the range of endwise adjustment of the pinion, which is possible without causing noise or spoiling the bearing of the teeth. This range of adjustment is greater than that obtained with straight-tooth bevel gears.

Skew Bevel Gears. — Skew bevel gears are used instead of regular bevel gears to connect two shafts which are offset or not in the same plane, and which are so close together that spiral or worm gearing cannot be satisfactorily applied. Skew bevel gears have straight teeth which bear on each other along a straight line, but these teeth do not converge to a common center or apex as in the case of ordinary bevel gears. In place of a single apex, there is a circle of apexes, so that accurate mathematical calculations of the various angles are complicated and involved. However, close approximations of the true angles and diameters can be arrived at by the use of simple formulas (see Machinery's Encyclopedia, Vol. V., page 367).

Types of Skew Bevel Gears. — There are two general types of skew bevel gears. One type has an ordinary bevel gear pinion, the oblique teeth being confined to the gear. The teeth of the other type are oblique in both the pinion and the gear. In each type, the pitch surface of the pinion is the frustum of a figure generated by the revolution of a straight line about the axis of the figure, the generating line lying in a plane parallel to a plane through the axis, and being neither parallel nor at right angles to the axis, *i.e.*, the figure is a hyperboloid of revolution.

Worm Gearing

Formulas for Worm Gearing. — Worm gearing is employed for two purposes: first, when power is to be transmitted under conditions making smoothness of action and a great reduction in velocity desirable, and in the second place, when a great increase in the effective power is required. In such cases, advantage is generally taken of the possibility of making the gearing self-locking. The service in the latter case is usually intermittent, and the waste of power due to the decreased efficiency of self-locking worm gearing is of less importance than for a steady drive. The table, "Rules and Formulas for Worm Gearing," gives all the directions necessary for calculating the dimensions. The notation used in the formulas is as follows:

P = circular pitch of wheel and linear pitch of worm;
l = lead of worm;
n = number of teeth or threads in worm;
S = addendum, or height of worm tooth above pitch line;
d = pitch diameter of worm;
D = pitch diameter of worm-wheel;
o = outside diameter of worm;
O = throat diameter of worm-wheel;
O' = outside diameter of worm-wheel (to sharp corners);
b = bottom or root diameter of worm;
N = number of teeth in worm-wheel;
W = whole depth of worm tooth;
T = width of thread tool at end;
α = face angle of worm-wheel;
β = helix angle of worm and gashing angle of wheel;
U = radius of curvature of worm-wheel throat;
C = distance between centers;
x = threaded length of worm.

When the number of threads n in the worm is spoken of, the number of threads per inch is not referred to, but the number of threads in the whole worm; that is, one, if it is single-threaded, four, if it is quadruple-threaded, etc.

Rules and Formulas for Worm Gearing

No.	To Find	Rule	Formula
1	Linear Pitch.	Divide the lead by the number of threads. — It is understood that by the number of threads is meant, not number of threads per inch, but the number of threads in the whole worm — one, if it is single-threaded, four, if it is quadruple-threaded, etc.	$P = \frac{l}{n}$
2	Addendum of Worm Tooth.	Multiply the linear pitch by 0.3183.	$S = 0.3183\,P$
3	Pitch Diameter of Worm.	Subtract twice the addendum from the outside diameter.	$d = o - 2\,S$
4	Pitch Diameter of Worm-wheel.	Multiply the number of teeth in the wheel by the linear pitch of the worm, and divide the product by 3.1416.	$D = \frac{NP}{3.1416}$
5	Center Distance between Worm and Gear.	Add together the pitch diameter of the worm and the pitch diameter of the worm-wheel, and divide the sum by 2.	$C = \frac{D + d}{2}$
6	Whole Depth of Worm Tooth	Multiply the linear pitch by 0.6866.	$W = 0.6866\,P$
7	Bottom Diameter of Worm.	Subtract twice the whole depth of tooth from the outside diameter.	$b = o - 2\,W$
8	Helix Angle of Worm.	Multiply the pitch diameter of the worm by 3.1416, and divide the product by the lead; the quotient is the cotangent of the helix angle of the worm.	$\cot \beta = \frac{3.1416\,d}{l}$
9	Width of Thread Tool at End.	Multiply the linear pitch by 0.31.	$T = 0.31\,P$
10	Throat Diameter of Worm-wheel.	Add twice the addendum of the worm tooth to the pitch diameter of the worm-wheel.	$O = D + 2\,S$
11	Radius of Worm-wheel Throat.	Subtract twice the addendum of the worm tooth from half the outside diameter of the worm.	$U = \frac{o}{2} - 2\,S$
12	Diameter of Worm-wheel to Sharp Corners.	Multiply the radius of curvature of the worm-wheel throat by the cosine of half the face angle, subtract this quantity from the radius of curvature, multiply the remainder by 2, and add the product to the throat diameter of the worm-wheel.	$O' = 2\left(U - U \times \cos\frac{\alpha}{2}\right) + O$
13	Minimum Length of Worm for Complete Action.	Subtract four times the addendum of the worm thread from the throat diameter of the wheel, square the remainder, and subtract the result from the square of the throat diameter of the wheel. The square root of the result is the minimum length of worm advisable.	$x = \sqrt{O^2 - (O - 4S)^2}$
14	Outside Diameter of Worm.	Add together the pitch diameter and twice the addendum.	$o = d + 2\,S$
15	Pitch Diameter of Worm.	Subtract the pitch diameter of the worm-wheel from twice the center distance.	$d = 2\,C - D$

Careful distinction must be made between the terms "pitch" and "lead." The term lead is defined as the distance which any one thread advances in one revolution of the worm, while the pitch, or, more correctly, the linear pitch, is the distance between the centers of two adjacent threads. The lead and pitch are equal for a single-threaded worm. For a double-threaded worm the lead is twice the linear pitch, and for a triple-threaded worm, three times the linear pitch.

The rules and formulas given are sometimes departed from. The throat diameter of the wheel and the center distance may have to be altered in some cases. For example, if worm-wheels with small numbers of teeth are made to the dimensions found from the rules and formulas, it will be found that the flanks of the teeth will be partly cut away by the tops of the hob teeth, so that a full bearing area is not available. This latter affects the worm-wheel drive seriously when there are less than twenty-five teeth in the worm-wheel. There are two ways of avoiding this difficulty. One is to increase the included angle of the sides of the worm thread and the angle of the hob. This departure from the standard form, however, may be avoided by an increase in the throat diameter of the wheel, and consequently in the center distance. (See paragraph, "Data for Turning Worm-wheel.") Some designers, again, claim to obtain better results in efficiency and durability by making the throat diameter of the worm-wheel smaller than the standard, when it is possible to do so without too much under-cutting. In no case, however, should the throat diameter be made so small as to produce more interference than is met with in a standard 25-tooth worm-wheel.

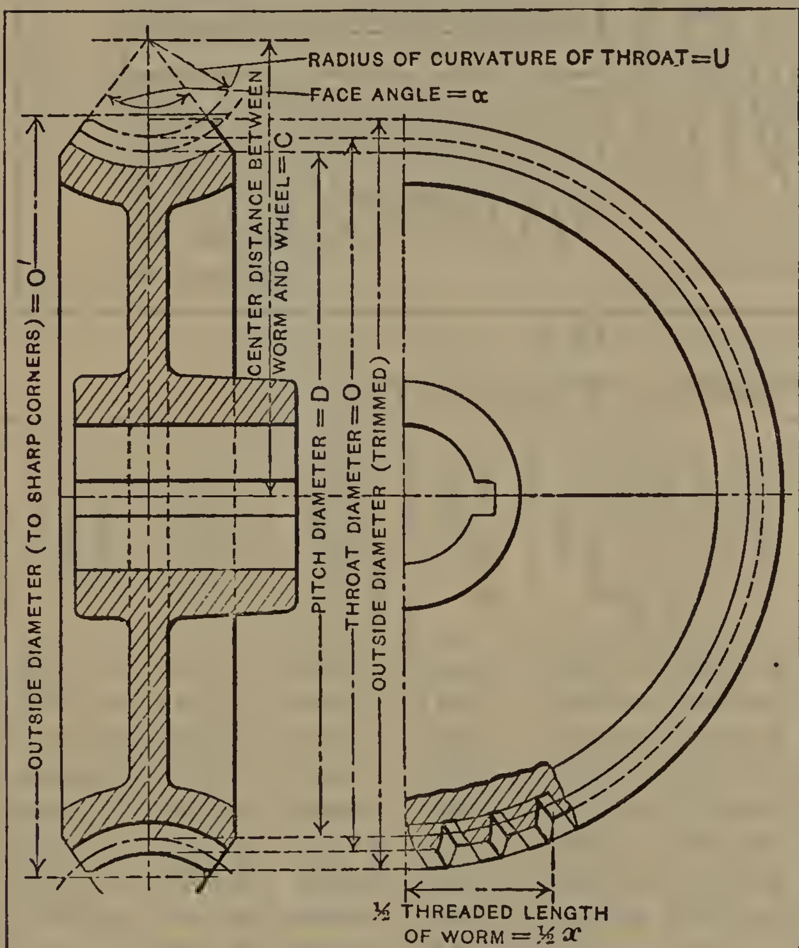


Fig. 1

The standard form of worm thread, measured in an axial section, as indicated in the illustration, Fig. 2, has the same dimensions as the standard form of involute rack tooth of the same linear pitch. It is not exactly of the same shape, however, as it is not rounded at the top, nor provided with fillets at the bottom. The thread is cut with a straight-sided tool having a square, flat end. The sides have an inclination with each other of 29 degrees, or 14½ degrees with the center line.

Rule (13) in the table gives the minimum length of the worm for complete action, or the *least* that should be used, and ordinarily the worm should be longer than the dimension found by the formula.

Worm hobs, in particular, should be long enough for the largest wheel that they are ever likely to have to cut. The face width of the worm-gear should not exceed one-half of the diameter of the worm.

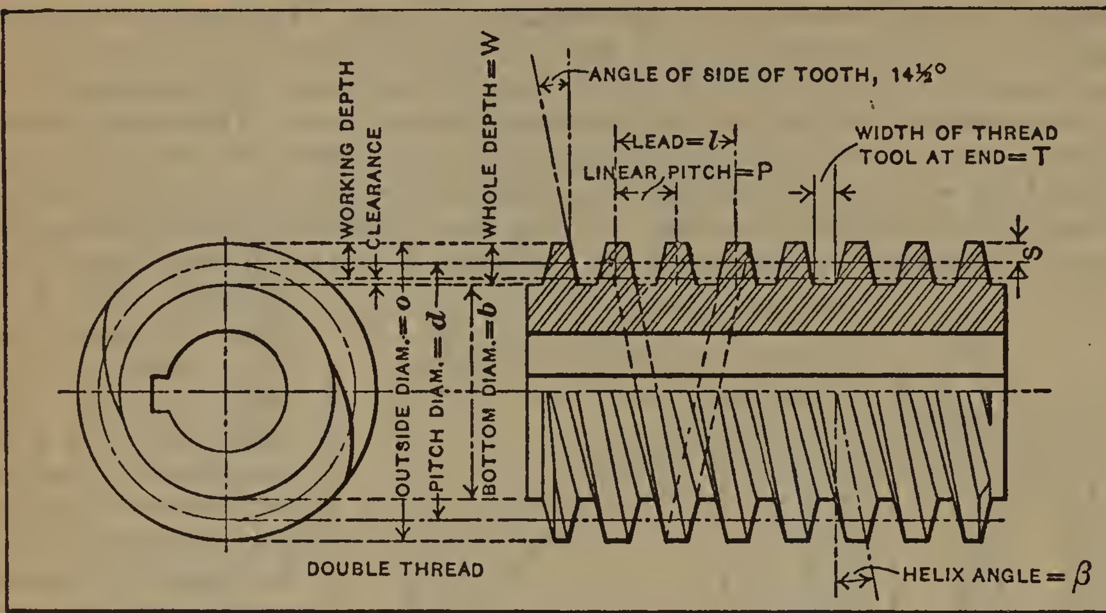

Fig. 2

Dimensions of Worm-thread Parts

Number of Threads per Inch	Circular or Linear Pitch, Inches	Circ. or Lin. Pitch, Decimal Equivalents	Height of Tooth above Pitch Line	Depth of Space below Pitch Line	Whole Depth of Tooth	Thickness of Tooth on Pitch Line	Width of Thread Tool at End	Width of Thread at Top
½	2	2.0000	0.6366	0.7366	1.3732	1.0000	0.6200	0.6708
4/7	1¾	1.7500	0.5570	0.6445	1.2015	0.8750	0.5425	0.5869
⅔	1½	1.5000	0.4775	0.5524	1.0299	0.7500	0.4650	0.5031
⅘	1¼	1.2500	0.3979	0.4603	0.8582	0.6250	0.3875	0.4192

Worms with Large Helix Angle. — When worms have a large helix angle (15 degrees or more) the dimensions of the thread should be measured at right angles to the helix. In such cases, the following changes should be made in the formulas in the table. Let:

$$P_n = \text{normal circular pitch} = P \times \cos \beta.$$

Then Formulas (2), (6) and (9) will be written as follows:

$$S = 0.3183\ P_n; \qquad W = 0.6866\ P_n; \qquad T = 0.31\ P_n.$$

When these changes are made all the other formulas will give correct results when used in their original form.

Example of Worm-gear Calculation. — Design a worm and wheel so as to utilize a hob already in stock for cutting the worm gear. The hob is double-threaded, ½ inch linear pitch, 2½ inches in diameter; the center distance is immaterial, but the worm-wheel ought to have about forty-five teeth, to obtain the required ratio. The calculations are as follows:

$$l = P \times n = 0.5 \times 2 = 1 \text{ inch};$$
$$S = 0.3183 \times 0.5 = 0.1591 \text{ inch};$$
$$d = 2.5 - 2 \times 0.1591 = 2.1818 \text{ inches};$$
$$D = (45 \times 0.5) \div 3.1416 = 7.1620 \text{ inches};$$
$$C = (2.1818 + 7.1620) \div 2 = 4.6719 \text{ inches};$$
$$W = 0.6866 \times 0.5 = 0.3433 \text{ inch};$$
$$b = 2.5 - 2 \times 0.3433 = 1.8134 \text{ inch};$$
$$\cot \beta = (3.14 \times 2.18) \div 1 = 6.845; \text{ hence } \beta = 8 \text{ degrees } 20 \text{ minutes, about};$$
$$T = 0.31 \times 0.5 = 0.155;$$
$$O = 7.1620 + 2 \times 0.1591 = 7.4802 \text{ inches};$$
$$U = (2.5 \div 2) - (2 \times 0.1591) = 0.9318 \text{ inch};$$
$$x = \sqrt{7.4802^2 - (7.4802 - 4 \times 0.1591)^2} = 3 \text{ inches, approximately}.$$

It is seldom necessary to calculate the diameter of the worm-wheel to sharp corners, if an accurate drawing is made of the worm-wheel. In the present case, the angle of face may be set at, say, 75 degrees, and the "trimmed diameter" may be scaled and will be found to be 7¾ inches. The face angle may, in general, be arbitrarily selected; 75 degrees is a good average angle, but as acute an angle as 60 degrees is frequently used, and sometimes the angle is made as large as 80 or even 90 degrees, although there is little advantage in carrying the gear around so great a portion of the circumference of the worm, especially when steep pitches are used. The width of the worm-wheel at the root of the teeth may be made from three-fifths to two-thirds of the outside diameter of the worm. In this case, then, the width at the root of the teeth may be made about 1½ inch, making the total width of the worm-gear blank about 1¾ inch.

Table for Calculating the Outside Diameter of Worm-wheels. — The regular formula for calculating the outside diameter (to sharp corners) of a worm-wheel is:

$$O' = 2\left(U - U \cos \frac{\alpha}{2}\right) + O,$$

in which O' = the outside diameter of worm-wheel to sharp corners; U = the radius of the curvature of worm-wheel throat; α = face angle of worm-wheel; O = throat diameter of worm-wheel.

By writing this formula in the form:

$$O' = 2\,U\left(1 - \cos\frac{\alpha}{2}\right) + O$$

it will be seen that the expression within the parentheses can be tabulated for various face angles, and such a table is given herewith. By using this table and calling the values found in the table for various angles, C, the formula takes the simple form:

$$O' = 2\,U \times C + O,$$

in which C can be found in the table for any angle from 30 to 90 degrees.

Table of Factors C Used in Worm-gear Formula

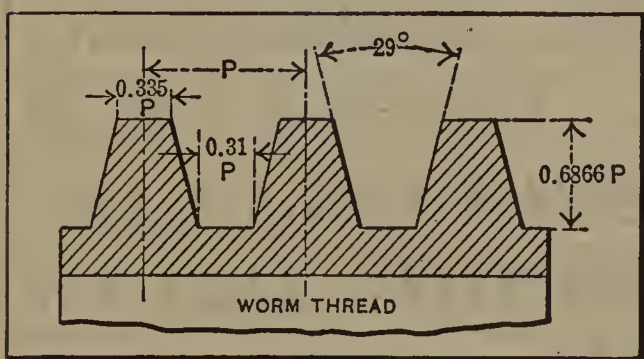
Worm-thread Helix Angles. — In the body of the tables, "Worm-thread Helix Angles," are found the approximate helix angles of worm threads, when the lead and the pitch-line diameter of the worm are given. For example, if the lead of the worm is 1 inch and its pitch-line diameter is 2 inches, then the angle of helix is approximately 9 degrees, as found from the tables. These tables can, of course, be used in a reverse order. If the thread angle in degrees and the pitch-line diameter are known, the approximate lead may be found, and if the angle and lead are known, the approximate diameter may be determined.

Assume, as an example, that it is required to find the diameter of a worm, the lead of which should be ½ inch, and the helix angle of which should not exceed 5 degrees. What would be the minimum pitch-line diameter of a worm that would meet these conditions? From the table it is found that the minimum pitch-line diameter would be 1⅞ inch.

Data for Turning Worm-wheel. — The throat diameter of a worm-wheel blank is the same as the outside diameter of a spur gear having the same number of teeth and pitch, and equals the pitch diameter plus twice the addendum; but if worm-wheels having less than 30 teeth are made according to this rule, the flanks of the teeth will be undercut by the hob and the worm will have a poor bearing below the pitch line. One method of avoiding this undercutting is to increase the throat diameter of the wheel blank in accordance with the following rule: To obtain the throat diameter, multiply the pitch diameter of the wheel by 0.937 and add to the product 4 times the addendum of the worm-wheel tooth. This diameter can also be obtained as follows: Multiply the product of the circular pitch and number of teeth in the worm-wheel by 0.298; then add 1.273 times the circular pitch. If it is necessary to keep the original center-to-center distance, the outside diameter of the worm must be reduced the same amount that the throat diameter is increased. When turning blanks, it is the general practice to simply reduce the central part of the throat to the required diameter, the remainder being left somewhat over size so that the tops of the teeth will be finished to the proper radius by the hob.

Data for Threading the Worm. — Worm threads have an included angle between the sides of 29 degrees, as shown by the sectional view. The width of the worm-thread tool at the end equals the linear pitch P of the worm (or circular pitch of the gear) multiplied by 0.31. To obtain the total depth of the worm thread, multiply the linear pitch P by 0.6866. When the thread is cut to this depth, it should have a width at the top equal to 0.335 of the linear pitch. To obtain the outside diameter of the worm blank, add twice the addendum to the pitch diameter of the worm. The addendum, or height of the worm tooth above the pitch line, equals the linear pitch multiplied by 0.3183. The threaded part of the worm should be long enough to make the action of the worm-wheel teeth upon the threads as complete as possible. To find the minimum length, use Rule (13) in the table "Rules and Formulas for Worm Gearing." Another common rule is to make the length of the worm equal to 6 times the circular pitch.



Threading Worms of Large Lead. — It is difficult to thread worms having a large lead or "quick pitch" on an ordinary lathe, because the lead-screw must be geared to run several times faster than the spindle, thus imposing excessive strains on the gearing. A common method of overcoming this difficulty is to mount a belt pulley on the lead-screw, beside the change gear and belt it to the countershaft; the spindle is then driven through the change gearing.

Gashing a Worm-wheel. — The teeth of worm-wheels, when cut in milling machines, are commonly formed by two operations; namely, gashing and hobbing. Gashing consists in cutting teeth around the periphery of the blank, which are approximately the shape of the finished teeth. This is done preferably by an involute gear cutter of a number and pitch corresponding to the worm-wheel. If a gear cutter is not available, a plain milling cutter, the thickness of which should not exceed 0.3 of the circular pitch, may be used. The corners of the cutter should be rounded to prevent removing the fillets of the teeth. The blank to be gashed is mounted on an arbor placed between the centers of the dividing head and tailstock, with the driving dog secured to prevent rotation. The table is adjusted laterally
